

Analysis of Kentucky Black Bass Genetic Results

December 2023

Section 1. Introduction

During the fall of 2022 and spring of 2023, the Kentucky Department of Fish and Wildlife Resources collected samples for a statewide bass genetics survey. From boat electrofishing surveys, each district took fin clips from black bass in 27 waterbodies across the state of Kentucky that may be impacted by undesirable genetics. There were two primary purposes of this study: (1) to establish baseline data on the amount of Florida Bass gene introgression into our Largemouth Bass populations; (2) to detect the presence of any Alabama Bass genetics within the Spotted Bass and Smallmouth Bass populations in Kentucky.

In general, 50 phenotypic Largemouth Bass per study lake were collected for genetic sampling. A fin clip was collected from each individual fish and stored in 95% ethanol for genetic analysis. Additionally, each bass was measured for total length, weighed, and in some cases the sagittal otoliths were removed for age and growth analysis. Fin clips were sent to the U. S. Fish and Wildlife Service's Southeast Conservation Genetics Lab at Auburn University to be analyzed by Dr. Nathan Whalen and his colleagues, using a panel of 30 diagnostic single nucleotide polymorphisms (SNP's) which were identified in earlier bass genetics studies (Li et al. 2015, Zhao et al. 2018). For more details on Dr. Whalen's methods, see his methodology and final report [here](#).

Alabama Bass look nearly identical to Spotted Bass and will readily hybridize with Spotted and Smallmouth Bass. Because of their similarity in appearance and their proclivity to hybridize, fin clips from 50 phenotypic Spotted Bass or Smallmouth Bass were also collected at Kentucky Lake, Lake Barkley, Herrington Lake, Laurel River Lake, Martin's Fork Lake, and Lake Cumberland. These fin clips were tested for the presence of Alabama Bass, Largemouth Bass, Smallmouth Bass, Shoal Bass, Spotted Bass, and Coosa Bass alleles. These lakes were chosen based on the presence of Spotted Bass within the system and their relative proximity to some Tennessee waters where Alabama Bass have already become established. Those fin clips were also analyzed by the Southeast Conservation Genetics Lab. See Figure 1 for a map showing the locations where black bass genetic samples were collected along with some sample information.

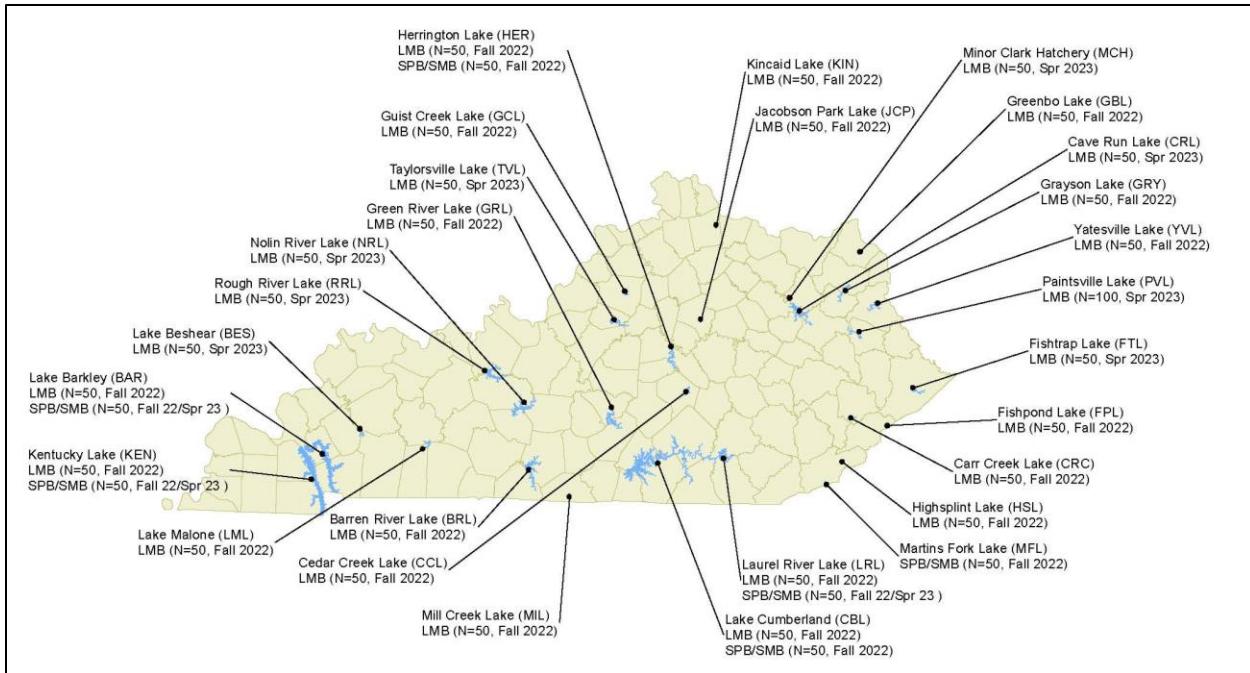

Figure 1. Map showing the locations of reservoirs where black bass genetic samples were collected for this study. The three-letter abbreviation for each lake is shown in parentheses, along with lake acreage, number of samples and collection times for analysis of potential Florida Bass introgression of Largemouth Bass (LMB) and potential Alabama Bass introgression of Spotted Bass and/or Smallmouth Bass (SPB/SMB).

Section 2. Results

A list of all 27 water bodies where Largemouth Bass were collected, their overall average percentages of Florida Bass alleles and Largemouth Bass alleles, the average percentages of heterozygous loci and coefficient of variation of Largemouth Bass alleles is provided in Table 1. The results presented for Minor Clark Fish Hatchery represent the Largemouth Bass broodfish used at the hatchery; a discussion of these results is provided in Section 4. More detailed descriptions of results for each of the 26 reservoirs are provided in Section 5. The full data set of results is provided in the appendices.

Broadly speaking, the results are congruent with other studies of the native ranges of these species which indicate that the natural intergrade zone does not extend into Kentucky. However, there are Largemouth Bass populations in a few reservoirs which have higher than expected levels of Florida Bass introgression. These reservoirs are very small and likely stocked with Florida Bass or hybrids at some point in the past. Furthermore, the geographic distribution of the reservoirs with high introgression does not support the hypothesis of a natural intergradation zone.

In recent published literature using various SNP panels, some authors have used 95% allelic frequency (Thongda et al. 2020) as the cutoff for “pure” members of a species. Others have used an average allelic frequency of 94% (Silliman et al. 2021) or even 90% (Dakin et al. 2015). The fact that 100% is not the

standard cutoff for a “pure” specimen is a testament to the uncertainty around species identification using these types of genetic tests.

Overall, the results from the 26 reservoirs tested supported our expectation that Largemouth Bass populations are composed of primarily pure or nearly pure fish. Of the lakes tested, 8 (30%) would be considered “pure” using a 95% cutoff and an additional 11 (73%) could be added if a 90% cutoff was used. It should be noted that the lakes chosen for testing were sampled explicitly because of a suspicion of the possible presence of Florida Bass alleles not at random. Despite this non-random selection, there still was a high percentage of reservoirs with pure or nearly pure Largemouth Bass observed

The coefficient of variation of the Largemouth Bass alleles is provided in Table 1 to highlight the degree of diversity within each waterbody’s sample. Waterbodies with a higher coefficient of variation indicate higher levels of allelic variation within the sample. High levels of variation within the sample are suggestive of a more recent introduction of Florida Bass alleles, whereas low levels of variation are suggestive of a pure population or an introduction which occurred much longer ago.

Unfortunately, the interpretation of these specific loci may be more imprecise than previously thought. Dr. Nathan Whalen believes our results, along with results he is getting from testing Largemouth Bass from other states, may indicate that some of these alleles are not truly diagnostic for differentiating between these two species across their entire range. There are some loci with high levels of heterozygosity in fish with otherwise homozygous allelic frequencies for the other loci. If this is the case, then the average allelic frequencies of LMB alleles would increase slightly and the actual percentage of “pure” Largemouth Bass in our samples would be slightly higher than what is being reported. Further testing in other areas of the species’ ranges should clarify the utility of these alleles in the future. It is also possible that more diagnostic alleles will be discovered in the future

No Alabama Bass alleles were discovered in the samples from our six tested waterbodies. While this is very encouraging, it is impossible to completely rule out the presence of Alabama Bass within the systems during the early phases of any new introductions. Testing for this invasive species will continue in the future.

Table 1. Results of genetic sampling of putative Largemouth Bass collected from 27 waterbodies across the state in fall 2022 or spring 2023. The sample size, average percentages of Largemouth Bass and Florida Bass alleles, the coefficient of variation of the Largemouth Bass alleles in the sample, the waterbody size, and the trout stocking rate (if applicable) are provided.

Waterbody	Valid Sample Size	Average % of LMB Alleles	Average % of FB Alleles	Average % of Heterozygous Alleles	Coefficient of Variation % of LMB Alleles	Lake Size (Acres)	Trout Stocked/ Acre
Nolin River Lake	49	97.5%	2.5%	4.1%	0.02	6017	
Lake Cumberland	50	97.3%	2.7%	5.0%	0.03	47688	
Lake Beshear	50	97.0%	3.0%	4.6%	0.03	819	
Cave Run Lake	50	95.8%	4.2%	7.7%	0.03	7880	
Jacobson Park Lake	50	95.2%	4.8%	8.9%	0.03	46	
Lake Barkley	47	94.7%	5.3%	9.9%	0.03	49083	
Grayson Lake	48	94.7%	5.3%	8.2%	0.04	1300	
Barren River Lake	50	94.7%	5.3%	9.3%	0.03	9674	
Green River Lake	49	94.3%	5.7%	10.1%	0.04	8181	
Lake Malone	50	93.5%	6.5%	10.6%	0.04	814	
Paintsville Lake	98	93.4%	6.6%	11.5%	0.04	996	19
Laurel River Lake	50	93.0%	7.0%	11.7%	0.06	5768	
Yatesville Lake	46	92.8%	7.2%	12.8%	0.04	2171	
Kentucky Lake	50	91.9%	8.1%	14.0%	0.06	11787	
Taylorsville Lake	50	91.5%	8.5%	14.2%	0.05	3014	
Herrington Lake	49	90.7%	9.3%	14.3%	0.07	2649	
Cedar Creek Lake	50	90.6%	9.4%	16.4%	0.04	792	
Kincaid Lake	50	90.5%	9.5%	15.6%	0.04	181	
Guist Creek Lake	50	89.8%	10.2%	16.3%	0.05	328	
Fishtrap Lake	50	87.3%	12.7%	22.2%	0.09	1038	
Carr Creek Lake	50	87.3%	12.7%	19.1%	0.06	521	
Rough River Lake	50	85.5%	14.5%	23.2%	0.07	4848	
Mill Creek Lake (Monroe Co.)	50	78.9%	21.1%	29.3%	0.20	95	
Greenbo Lake	47	74.8%	25.2%	32.8%	0.09	176	72
Fishpond Lake	50	54.2%	45.8%	43.9%	0.14	28.8	125
Highsplint Lake	50	37.6%	62.4%	40.4%	0.17	6	458
Minor Clark Hatchery	50	86.2%	13.8%	22.7%	0.13		

Section 3. Future Management

While we did not expect these results would support stocking of Florida Bass genetics in any way, they do prompt questions. Some of the small lakes with higher percentages of Florida Bass alleles have a history of producing some large bass. Most notably, Highsplint Lake produced our current state record. Although that fish was not tested for genetics, based on the variation of the 50 fish sample in this study it is very likely that the record fish contained a similarly high percentage of Florida Bass genetics as other

fish within our sample. While it is possible that the most recent state record was an F1 or pure Florida Bass, based on our genetic analysis it is more likely that any Florida Bass stocking would have occurred many years ago and that there would be no F1's or pure Florida Bass currently present in Highsplint Lake. Confounding this issue, Highsplint Lake is a small 6-acre lake with a stunted bass population that receives trout stockings at a very high rate (>450/acre). It is typical in these stunted populations for there to be 1 or 2 large individuals who achieve large sizes because they are far less gape limited than the remaining stunted population. Their larger size enables them to be cannibalistic. The stocking of trout also tends to dramatically increase the trophy potential of those few large individuals. The 9-in stocked trout are often too large for the stunted bass to consume, but the trout are readily consumed by those few larger bass during the summer months when the trout can become lethargic or even die. Whether the bass genetics and/or the heavy stocking of rainbow trout in the lake resulted in the production of that large bass is a question still to be answered and unfortunately the other lakes with the highest percentages of Florida Bass alleles in our sample are also heavily stocked with trout which complicates any direct comparison with other water bodies (however, a sample of fish will be tested from Wood Creek Lake, which also receives trout stockings and was home of the Largemouth Bass state record immediately prior to the Highsplint Lake fish). Regardless of that uncertainty, the production of some trophy fish in those water bodies is a fact deserving of more investigation.

While there are reasons to continually evaluate the potential for Florida Bass stocking to increase trophy bass numbers in Kentucky, there are also reasons to be highly cautious. Florida Bass genetics have been stocked into multiple states over the past 50 years and the research shows that it only resulted in larger fish in certain situations. When stocked in areas too far outside of their native range they have been shown to perform worse than the native Largemouth Bass. Other states to our south like Oklahoma, Arkansas, and Tennessee use the climate metric of 3400 heating degree days or less as the farthest north they will stock Florida Bass genetics. No waterbody in Kentucky experiences less than 4000 heating degree days in an average year, so our climate is still unsuitable according to the prior research. Furthermore, Florida Bass will readily hybridize with our native Largemouth Bass. This means that any stocking of Florida Bass genetics into Kentucky waterbodies will result in permanent changes to our Largemouth Bass population's genetic composition. The large reservoirs in Kentucky are still dominated by pure Largemouth Bass with low or no levels of introgression. If we had observed widespread levels of introgression then we could have concluded that there would be less risk, but also little advantage, to stocking additional Florida Bass genetics in Kentucky. The relative purity of our samples allows us to conserve our native bass genetics. These genetics evolved here and are well adapted to the local conditions. Many biologists and anglers feel strongly that preserving native bass genetics should be the highest conservation priority.

With regards to future management practices, to ensure that the above concerns receive the respect that they deserve, we will be expanding our study to better understand the potential impacts of stocking Florida Bass genetics into Kentucky waterbodies. Although we have tested many waterbodies, a study of additional lakes statewide would provide a better understanding of our Largemouth Bass genetics. Furthermore, by examining the existing genetic diversity in some of our introgressed waterbodies we may be able to compare the fitness of hybrid stocks against the fitness of native stocks without the permanent risks associated with any stocking experiments.

Experimenting with Florida Bass stockings on even a relatively small scale carries significant risk. First, conducting an experiment in small ponds may not accurately reflect what would occur in larger

waterbodies, potentially leading towards the wrong conclusion and a costly and ineffective strategy. Second, any experiment risks the possibility of escapement into nearby waterbodies. Third, a stocking experiment like this would be best conducted in a water body which is already producing trophy-size bass, meaning one or more trophy bass lakes would be put at risk of permanent negative effects to the bass population due to outbreeding depression. For example, Lake Beshear routinely produces a balanced population with consistent catches of trophy bass and is among the purest Largemouth Bass populations in the state; conducting an experiment here would put this population at irreversible risk.

Although we do have evidence of some large fish in our highly introgressed waterbodies, that evidence is currently limited to smaller waterbodies which receive high rates of trout stocking. Aside from a few trophy fish, those populations are stunted and otherwise unremarkable. The evidence in other states suggests that stocking Florida Bass genetics in areas with more than 3400 heating degree days is ineffective at increasing numbers of trophy fish. Climate, fertility, forage availability, and other factors all play a part in the success of Florida Bass genetics. Some evidence also suggests that mixing Florida Bass genetics with Largemouth Bass genetics can cause lower survival, reduced reproductive ability, and reduced catchability. Even states to our south with more suitable climates do not stock every available waterbody due to the inherent risks to native genetic stocks. Of greatest concern is the inability to reverse any genetic changes resulting from the stocking of Florida Bass in these reservoirs. If the results of Florida Bass stockings were damaging to the bass fisheries in these reservoirs, it would be permanent.

Finally, there has been recent rapid expansion of black bass genetic testing across the eastern US and in the Chinese aquaculture system (Cheng-Fei Sun et al. 2023, Dong et al. 2019). This is greatly increasing the understanding of the distinct lineages of Largemouth Bass while also opening new lines of research into the importance of particular genes which may be linked with relevant traits like growth rate, maximum size, immune system traits, aggression, reproductive ability, and environmental suitability. It is likely that the future of bass stocking will focus on the incorporation of these particular genes rather than rudimentary mixing of different black bass species. This increased understanding of Largemouth Bass lineages also supports the strategy of taking the conservative approach of not irreversibly mixing different species.

Section 4. Minor Clark Hatchery Testing

In addition to the 26 public waterbodies, broodfish at Minor Clark Fish hatchery were also tested. This hatchery is the only one which produces Largemouth Bass for the department. Each tested broodfish was tagged with a passive integrated transponder (PIT tag). PIT tags will allow us to track the genotypes of any individual broodfish used in the rearing process in the future. The results at this location revealed the presence of higher levels of Florida Bass introgression in some fish, while others were pure or nearly pure Largemouth Bass. The original source of the hatchery bass is unknown, but these results suggest that they may have been sourced from somewhere out of state early in the hatchery's history. We know this as some of the Largemouth Bass progeny are kept and propagated at the hatchery for new broodfish and no new broodfish from an outside source have intentionally been added in many years. While most of the population had low genetic variation, a few highly introgressed individuals in this sample suggest a very recent small introduction of some Florida Bass genetics. While the exact source of those highly introgressed individuals is unknown, we theorize that these Florida Bass genetics escaped during an experiment conducted on Florida Bass growth at the hatchery from 2015 through

2017. These results highlight the escapement issues which can arise even when conducting non-native bass experiments in controlled test ponds.

In anticipation of this testing, bass rearing and stocking was suspended at Minor Clark Hatchery in 2022. However, it is likely that fish with some small degree of introgression were stocked in a few water bodies in prior years. Only 50 broodfish have been tested so far, but many more will be tested in the near future. Once testing is completed only broodfish with known genotypes of 95% or higher Largemouth Bass alleles will be used for rearing.

Additionally, because each broodfish has a unique PIT tag, it could allow a strategy of rearing and stocking more aggressive bass. Prior research has shown that aggression is a heritable trait which can be selected for in hatchery settings by choosing broodfish which have shown a tendency to be more easily caught by angling. Research also shows that aggressive traits like catchability tend to decline in populations exposed to high levels of fishing pressure, so this may be a way to stock bass which are more likely to be caught by anglers than wild fish. The implementation of this strategy would have a relatively low cost since each fish will already be uniquely tagged. However, to our knowledge, this approach has not been attempted in a large water body and it would likely be difficult to achieve noticeable changes in catchability on a population level.

Section 5. Waterbody Specific Results of Florida Bass Introgression Testing

The following information was prepared by District Fisheries Biologists across the state on the 26 lakes tested. Further questions or clarity regarding the information presented should be referred to the local District Fisheries Biologist for that water body.

Eastern Fisheries District

Paintsville Lake: Genetic sampling originally took place in the fall of 2022. However, it was decided that collecting samples in spring of 2023 would be more useful since those fish could also provide age and growth data through the collection of otoliths from those fish. One hundred Largemouth Bass were randomly selected from the Spring 2023 sample for testing.

On average, Largemouth Bass alleles accounted for 93.4% of the total Largemouth Bass and Florida Bass alleles. A few individual fish (14 of the 100) had Florida Bass allele percentages over 10% and two notable outliers had Florida Bass allele percentages of 21.4%.

- Items of note about Paintsville Lake: Paintsville Lake is a 1,001-acre USACE flood control and water supply reservoir located in Johnson and Morgan counties. The dam was completed in 1983 on Paint Creek, a tributary of the Levisa Fork of the Big Sandy River. The results at Paintsville Lake were not an outlier from the rest of our large waterbodies but were still somewhat unexpected. In 2022 a group of anglers partnered with the new Fisheries Management Division of Major League Fishing to collect genetic samples at a Largemouth Bass tournament held at Paintsville Lake. They conducted swab testing on 97 bass and sent to them to Dr. Eric Peatman's laboratory at Auburn University. The results showed much higher levels of Florida Bass introgression at Paintsville Lake than our recent results from the fin clip testing in 2023. The angler-caught bass genetic results showed an average of only 44.2% Largemouth Bass

alleles and 55.7 % Florida Bass alleles. The relatively high percentage of Florida Bass alleles alone would have made it an outlier from the rest of Kentucky's major reservoirs, but even more interestingly the coefficient of variation of the Largemouth Bass allele percentage was 0.52 which is much higher than any waterbody in our sample. The percentage of Florida Bass alleles in the angler-caught sample ranged from 98% down to 2% with several pure (>95%) Florida Bass individuals. Based on that high variation alone, it would have indicated a very recent, major, illegal introduction of Florida Bass into Paintsville Lake to be able to affect the genetics to that degree. However, the latest genetic testing results detailed in this report indicate a pure or nearly pure Largemouth Bass population which has not received any major influxes of Florida Bass genetics. Throughout its history, 1991 and 1992 were the only years the KDFWR stocked Largemouth Bass in Paintsville Lake. Paintsville Lake is also home to a variety of invasive aquatic vegetation including Brazilian Elodea and Hydrilla.

Yatesville Lake: Fifty Largemouth Bass samples collected from 12 locations in the upper, middle and lower sections of the lake were submitted for testing in the fall of 2022.

On average, Largemouth Bass alleles accounted for 92.8% of the total Largemouth Bass and Florida Bass alleles. Thirteen fish tested had Florida Bass alleles over 10%, but none more than 13.3%.

- Items of note about Yatesville Lake: Yatesville Lake is a 2,282-acre USACE flood control reservoir constructed between 1986 and 1989 on Blaine Creek, a tributary of the Big Sandy River. Yatesville Lake is located in Lawrence County. The lake has not had any previous genetic testing of Black Bass. Yatesville Lake was stocked by the KDFWR with Largemouth Bass in 1991, 2006, 2009, and 2012.

Fishtrap Lake: One hundred fish were randomly selected from spring electrofishing samples at Fishtrap Lake in the spring of 2023 for genetic testing. Otoliths were also collected from these fish for age and growth determinations. Only 50 of the 100 fin clips were sent out for DNA analysis and the others remain preserved in 100% ethanol for further testing if needed.

On average, Largemouth Bass alleles accounted for 87.3% of the total Largemouth Bass and Florida Bass alleles. Thirty-four bass had more than 10% Florida Bass alleles and 6 bass had greater than 20% Florida Bass alleles. The level of variation in this sample is suggestive of a more recent introduction of Florida Bass genetics within the system.

- Items of note about Fishtrap Lake: Fishtrap Lake is a 1,071-acre USACE flood control reservoir constructed between 1962 and 1968 on the Levisa Fork, a tributary of the Big Sandy River. It is located in Pike County. The lake has not had any previous genetic testing of black bass. Fishtrap Lake was stocked by the KDFWR with Largemouth Bass in 1969, 2008-2010, 2013, 2014, 2017, 2018, 2020, and 2021.

Carr Creek Lake: Fifty fish were randomly selected by electrofishing in the fall of 2022 for genetic testing. Samples were collected from 2 locations including upper and lower sections of the lake.

On average, Largemouth Bass alleles accounted for 87.3% of the total Largemouth Bass and Florida Bass alleles. Twenty-seven bass had greater than 10% Florida Bass alleles and 4 bass had greater than 20% Florida Bass alleles. The low level of variation suggests that the Florida Bass introduction happened many years ago.

- Items of note about Carr Creek Lake: Carr Creek Lake is a 537-acre USACE flood control reservoir located in Knott County. Its dam was completed in 1976 and is located 8.8 miles above the mouth of Carr Fork, a tributary of the North Fork of the Kentucky River. This lake has not had any previous genetic testing of black bass. The lake has been stocked by the KDFWR with Largemouth Bass multiple times over its history due to poor recruitment. Years of stocking include 1976, 1993-1994, 1996-1997, 1999-2011, 2013-2015, and 2018-2019. In recent years, a significant expansion of invasive vegetation (Hydrilla) has led to an increase in natural recruitment and no additional stockings of Largemouth Bass have been required.

Fishpond Lake: Fifty fish were randomly collected by electrofishing in the fall of 2022 for genetic testing. Samples were collected from the shoreline at multiple locations throughout the entire lake.

On average, Largemouth Bass alleles accounted for 54.2% of the total Largemouth Bass and Florida Bass alleles. This population has among the highest levels of introgression in the state. Only 9 of the sampled fish had more than 60% Largemouth Bass alleles. The level of variation suggests that Florida Bass genetics were introduced here many years ago, but at a level that heavily influenced the bass genetics.

- Items of note about Fishpond Lake: Fishpond Lake is a 32-acre lake owned and operated by the Letcher County Fiscal Court. The KDFWR has a memorandum of agreement (MOA) with Letcher County to manage the fishery and stock fish as needed while keeping the lake open to the public and subject to enforcement of statewide fishing regulations. The initial stocking of Fishpond Lake was performed privately, prior to the MOA between the KDFWR and Letcher County Fiscal Court. The KDFWR currently stocks Rainbow Trout annually at a rate of 125 fish/acre. Largemouth Bass were stocked by KDFWR in 1965, 1979, 1987, and 2016. This lake has not had any (known) previous black bass genetic testing.

Highsplint Lake: Fifty fish were randomly collected by electrofishing in the fall of 2022 from all areas the lake. Fin clips from those fish were submitted for genetic testing

On average, Largemouth Bass alleles accounted for 37.6% of the total Largemouth Bass and Florida Bass alleles. This is the highest level of Florida Bass introgression observed thus far in the state of Kentucky. No fish from our sample had greater than 50% Largemouth Bass alleles. Although the overall variation observed here was the highest, the lack of major outliers is still suggestive of an introduction many years ago.

- Items of note about Highsplint Lake: Highsplint Lake is a 6-acre lake owned and operated by the Harlan County Fiscal Court. The KDFWR has a memorandum of agreement (MOA) with Harlan County to manage the fishery and stock fish as needed while keeping the lake open to the public and subject to enforcement of statewide fishing regulations. The KDFWR previously stocked Rainbow Trout annually at a rate of 458 fish/acre. The Rainbow Trout stocking rate was recently lowered to 375 fish/acre. Highsplint Lake produced our current state record Largemouth Bass. While that fish was not tested for genetics, based on the variation of the 50-fish sample in this study it is very likely that record fish contained similarly high percentages of Florida Bass genetics as other fish within our sample from the lake. Whether the bass genetics and/or the heavy stocking of Rainbow Trout in the lake resulted in the production of that large bass is a question still to be answered. The lake itself was privately owned prior to 1993 and was likely

stocked with Florida Bass or hybrids when it was privately owned. The KDFWR has not stocked any additional Largemouth Bass in this lake. This lake has not had any (known) previous black bass genetic testing.

Southeastern Fisheries District

Lake Cumberland: Fifty Largemouth Bass were randomly collected by electrofishing from four areas of the lake including Fishing Creek, Faubush Creek, Lily Creek, and the Dam in the fall of 2022. These areas are the standardized sampling locations used for black bass assessment on Lake Cumberland. Fin clips from these fish were submitted for genetic testing.

On average, Largemouth Bass alleles accounted for 97.3% of the total Largemouth Bass and Florida Bass alleles. Only 6 of the 50 fish had a Florida Bass allele percentage over 5%, and only one was greater than 15%. This is one of the purest populations of Largemouth Bass in the state.

- Items of note about Lake Cumberland: Lake Cumberland is a 47,698-acre USACE flood control reservoir located in Wayne, Russell and Pulaski counties. The lake was first stocked with Largemouth Bass in 1978. Additional stockings of Largemouth Bass by the KDFWR occurred in 2010, 2012, 2014, 2015, 2017, and 2019. Given the size of Lake Cumberland, stocking rates are generally low, with stocking rates being less than two fish per acre in all years, except 2010 when bass were stocked at six fish per acre.

Laurel River Lake: Fifty Largemouth Bass were randomly collected by electrofishing in the fall of 2022 from 7 areas including Craigs Creek, Marsh Branch, the Dam, Eagle Nest, Rogers Creek, Spruce Creek, and 312 Bridge. Fin clips from those fish were submitted for genetic testing. Additional fin clips were also collected during an age and growth study in the spring of 2023, but those clips have not been tested.

On average, Largemouth Bass alleles accounted for 93.0% of the total Largemouth Bass and Florida Bass alleles. Of the 50 fish tested, 26 had Florida Bass alleles over 5% and ten had more than 10% Florida Bass alleles.

- Items of note about Laurel River Lake: Laurel River Lake is a 5,768-acre USACE flood control reservoir located in Laurel and Whitley counties. Laurel River Lake was first stocked in 1973 at a rate of 2 fish per acre. As part of the Bass Stocking Initiative (BSI), Laurel River Lake is a Priority One lake in the program and has been stocked numerous times since the inception of the program, including 2005-2008, 2010-2011, and 2022.

Cedar Creek Lake: Fifty fish were randomly selected by electrofishing in the fall of 2022 from two locations in the lake including the upper and lower sections. These areas are the standardized sampling locations used for Largemouth Bass on Cedar Creek Lake. Fin clips from these fish were submitted for genetic analysis.

On average, Largemouth Bass alleles accounted for 90.6% of the total Largemouth Bass and Florida Bass alleles. Twelve of the 50 fish tested had a Florida Bass allele percentage over 10%.

- Items of note about Cedar Creek Lake: Cedar Creek Lake is a 788-acre reservoir in Lincoln County. Cedar Creek Lake was built by the KDFWR in 2002 and was stocked with Largemouth

Bass in 2003 when the lake was first impounded. In total, 45,000 fry, 16,250 fingerlings, and 2,500 adult Largemouth Bass were stocked to create the initial bass population. Although Cedar Creek Lake is a Priority One Lake in the BSI program, no additional bass have been stocked into the lake as natural reproduction has been adequate to support the bass population.

Northeastern Fisheries District

Cave Run Lake: Fifty Largemouth Bass were randomly collected by electrofishing from 3 different areas on the lake in the spring of 2023 and small fin clips were taken for genetic analysis. Otoliths were also collected so that genetic makeup could be matched with age and growth characteristics at a later time.

On average, Largemouth Bass alleles accounted for 95.8% of the total Largemouth Bass and Florida Bass alleles. Cave Run Lake is one of the purest Largemouth Bass Lakes in the state. In fact, only 13 of the 50 fish had a Florida Bass allele percentage over 5%, and only one was greater than 10%.

- Items of note about Cave Run Lake: Cave Run Lake is a 7,977-acre USACE flood control reservoir located in Bath, Menifee, Rowan, and Morgan counties. Cave Run Lake is one of the better bass producing lakes (determined by catch rates of age-1 fish) in the state and hasn't had the recent need for outside stocking. The lake was stocked frequently in the past, with stockings occurring in 1974, 1980-1982, 1984-1989, 1991-1994, 2001, 2003, 2005, 2009, and 2011.

Grayson Lake: Fifty Largemouth Bass were randomly selected by electrofishing from 3 different areas on Grayson Lake in the fall of 2022 and small fin clips were taken for genetic analysis.

On average, Largemouth Bass alleles accounted for 94.7% of the total Largemouth Bass and Florida Bass alleles and categorize the Grayson Lake Largemouth Bass population as pure. Of the 50 fish collected only nine had a Florida Bass allele percentage over 10% and 20 had a Florida Bass allele percentage over 5%.

- Items of note about Grayson Lake: Grayson Lake is a 1,512-acre USACE flood control reservoir located on the Little Sandy River in Carter and Elliott counties. Grayson Lake has historically had a stunted bass population. KDFWR stocked Largemouth Bass into Grayson Lake in 1976, 1977, 1982, 1989, 1990, 1998, 1999-2004, 2008, and 2009.

Greenbo Lake: Fifty Largemouth Bass were randomly selected by electrofishing across the entirety of the lake in the fall of 2022 and fin clips were collected for genetic analysis.

On average, Largemouth Bass alleles accounted for 74.8% of the total Largemouth Bass and Florida Bass alleles. Of lakes that were tested, this population has the third highest percentage of Florida Bass alleles. The KDFWR's first Largemouth Bass stocking in Greenbo Lake occurred in 1956 and additional stockings occurred in 1964, 2007, 2008, 2010, 2011, 2015, 2016 (part of Trophy Fish Program stocking), 2019, 2021, and 2022. Additionally, Greenbo Lake was privately owned prior to state park ownership and the origins of the initially stocked fish are unknown.

- Items of note about Greenbo Lake: Greenbo Lake is a 179-acre KDFWR-owned lake located in Greenup County. It is the home of 2 previous state record Largemouth Bass (an 11lb, 10oz. fish caught in 1965 and a 13lb, 8oz. fish caught in 1966). It is currently stocked with both Rainbow

(61 fish/acre) and Brown (11 fish/acre) trout. Rainbow Trout stockings started in 1965, the same year the first state record was caught. Brown Trout stockings began in 2020.

Central Fisheries District

Guist Creek Lake: Fifty Largemouth Bass were randomly collected by electrofishing throughout the entire lake in fall of 2022. Fin clips were taken from these fish for genetic analysis.

On average, Largemouth Bass alleles accounted for 89.9% of the total Largemouth Bass and Florida Bass alleles. Twenty-two of the 50 fish had a Florida Bass allele percentage over 10%, and four were greater than 15%. Only 8 of the 50 fish were considered pure Largemouth Bass, suggesting that the introduction of Florida Bass genetics was not recent.

- Items of note about Guist Creek Lake: Guist Creek Lake is a 317-acre KDFWR-owned lake located in Shelby County. It is located on Guist Creek which is a tributary to Brashears Creek that flows into the Salt River downstream of Taylorsville Lake. Due to poor year classes, Guist Creek Lake has been stocked on a regular basis with stockings occurring in 1961, 1963, 1964, 1975-1977, 1979-1995, 2002-2004, 2007, 2009-2012, 2014, 2018, 2019, 2021, and 2022. It is suspected that illegal stocking has occurred over the years due to the sporadic presence of Spotted Bass (≥ 12.0 in) and Smallmouth Bass (≥ 18.0 in) in our samples. Guist Creek Lake is one of the better quality-largemouth bass fisheries in the Central Fisheries District.

Taylorsville Lake: Fifty Largemouth Bass were collected by electrofishing from 3 locations (Big Beech Creek, Ashes Creek and Chowning Lane areas) in the spring of 2023. Fin clips were taken for genetic analysis.

On average, Largemouth Bass alleles accounted for 91.5% of the total Largemouth Bass and Florida Bass alleles. Of the 50 fish tested, 17 were considered pure Largemouth Bass, 12 had a Florida Bass allele percentage over 10%, and 5 had more than 15% Florida Bass alleles.

- Items of note about Taylorsville Lake: Taylorsville Lake is a 2,936-acre USACE flood control reservoir located in Spencer, Anderson, and Nelson counties. Taylorsville Lake was formed by impoundment of the Salt River upstream of Taylorsville, KY, and is a direct tributary to the Ohio River. Due to poor year classes, Taylorsville Lake has been stocked routinely with Largemouth Bass. Stocking years include 1983, 1985-1992, 2000-2008, 2010, 2011, 2014, 2015, 2017-2019, 2021, and 2022. In terms of usage (angler and recreational), Taylorsville Lake is one of the most popular lakes in the Central Fisheries District.

Herrington Lake: Fifty Largemouth Bass were randomly selected by electrofishing from four areas (Chimney Rock, Gwinn Island, Stoney Cove, and Upstream of Dunn Island) for genetic testing in the fall of 2022. However, results were only returned from the lab for 49 of the 50 samples submitted.

On average, Largemouth Bass alleles accounted for 90.7% of the total Largemouth Bass and Florida Bass alleles. Of the 49 fish tested, 13 had a Florida Bass allele percentage over 10%, 1 had a Florida Bass allele percentage of 40%, and 13 were considered pure Largemouth Bass. The high Florida Bass allele percentage in the one fish suggests there may have been some recent introductions of Florida Bass genetics into the lake.

- Items of note about Herrington Lake: Herrington Lake is a 2,657-acre reservoir located in Mercer, Boyle, and Garrard counties. Herrington Lake is the oldest lake in the Central Fisheries District and is owned by Kentucky Utilities. Herrington Lake was created by impounding the Dix River about 3 miles upstream of its confluence with the Kentucky River. The KDFWR has stocked Largemouth Bass into the lake in 1971, 2003, 2004, 2007, 2010, 2012, 2014, 2016-2019, and 2022.

Jacobson Park Lake: Fifty Largemouth Bass were randomly selected by electrofishing throughout the entire lake in the fall of 2022 for genetic analysis.

On average, Largemouth Bass alleles accounted for 95.2% of the total Largemouth Bass and Florida Bass alleles. Only 3 of the 50 fish tested had a Florida Bass allele percentage over 10% and 34 were considered pure Largemouth Bass. This population is among the purest in the state.

- Items of note about Jacobson Park Lake: Jacobson Park Lake is a small, 46-acre park lake located in Fayette County. Jacobson Park Lake is owned by Kentucky American Water and is directly connected to Lake Ellerslie Fishing Club via a large culvert. Lake Ellerslie Fishing Club has stocked 13,213 F-1 Tiger Bass from 2005-2022; however, based on the genetic results, Florida alleles were found at a very low occurrence in Jacobson Park Lake. Jacobson Park Lake is currently enrolled in the FINs (Fishing In Neighborhoods) program and has not been stocked with Largemouth Bass since 2008. Prior to 2008, the lake was stocked with Largemouth Bass in 1981-1985, 1993, 1995-1997, 1999-2004, and 2007.

Kincaid Lake: Fifty Largemouth Bass were randomly selected by electrofishing throughout the entire lake in the fall of 2022. Fin clips were taken from these bass for genetic analysis

On average, Largemouth Bass alleles accounted for 90.5% of the total Largemouth Bass and Florida Bass alleles. Of the 50 fish sampled, 19 had a Florida Bass allele percentage over 10%, 1 had a Florida Bass allele percentage over 15%, and 7 were considered pure Largemouth Bass.

- Items of note about Kincaid Lake: Kincaid Creek was impounded to create 162-acre Kincaid Lake and it is a direct tributary to the Licking River. Kincaid Lake is owned and managed by the KDFWR and is located in Pendleton County. The Kincaid Lake bass population exhibits slow growth and older ages compared to bass populations in other lakes in the Central Fisheries District. The only Largemouth Bass stockings in Kincaid Lake occurred in 1972 and 2010. In 2011, muscle and liver samples were used to evaluate the genetic composition of Largemouth Bass at Kincaid Lake. A total of 5 loci were analyzed resulting in 95% to 98% of the sample expressing Largemouth Bass alleles while Florida Bass alleles ranged from 2% to 5%.

Southwestern Fisheries District

Barren River Lake: Fifty Largemouth Bass were randomly collected by electrofishing from 4 different areas on the lake in the fall of 2022. Sagittal otoliths were also collected so that genetic makeup could be matched with age and growth characteristics at a later time.

On average, Largemouth Bass alleles accounted for 94.7% of the total Largemouth Bass and Florida Bass alleles and categorize the Barren River Lake Largemouth Bass population as pure. Twenty-five of the 50

fish had a Florida Bass allele percentage over 5%, and only one had a Florida Bass allele percentage greater than 10%.

- Items of note about Barren River Lake: Barren River Lake is a 9,934-acre USACE flood control reservoir located in Allen and Barren counties. Barren River Lake is one of the better bass producing lakes in the state as determined by catch rates of age-1 fish. Barren River Lake has only been stocked with Largemouth Bass in 2019 and 2021.

Green River Lake: Fifty Largemouth Bass were randomly selected by electrofishing from 4 different areas on the lake in the fall of 2022. Fin clips were taken from these fish for genetic analysis.

On average, Largemouth Bass alleles accounted for 94.7% of the total Largemouth Bass and Florida Bass alleles, so the population at Green River Lake is considered pure. Of the 50 fish collected, 5 had a Florida Bass allele percentage over 10% and 22 had a Florida Bass allele percentage over 5%.

- Items of note about Green River Lake: Green River Lake is an 8,518-acre USACE flood control reservoir located in Taylor and Adair counties. Due to multi-port discharge capabilities on the reservoir, Green River Lake has a higher likelihood of fish escapement/emigration than most KY USACE reservoirs (Louisville District), as discharge ports remain above the thermocline for the entirety of the reservoir stratification period. Green River Lake has only been stocked with Largemouth Bass in 1977 and 2006.

Mill Creek Lake (Monroe County): Fifty Largemouth Bass were randomly selected by electrofishing across the entirety of the lake in the fall of 2022. Fin clips were taken for genetic analysis.

On average, Largemouth Bass alleles accounted for 78.9% of the total Largemouth Bass and Florida Bass alleles. Compared to our other tested waterbodies, this population has a relatively high number of Florida Bass alleles. It also has the highest levels of variation of all the lakes tested, suggesting that an introduction may have occurred more recently than in other introgressed waterbodies.

- Items of note about Mill Creek Lake: Mill Creek Lake is a 95-acre lake located in Monroe County and is owned by the City of Thompkinsville, but managed by the KDFWR. Due to proximity to the Cumberland River and Dale Hollow Lake, the lake's propensity to receive angler introductions (as evidenced by observations of striped bass, sauger, white bass, alewives, spotted bass, and smallmouth bass during electrofishing surveys over the years) is likely higher than most. Mill Creek Lake was stocked with bass in 2016.

Northwestern Fisheries District

Rough River Lake: In total, 142 fin clips were collected from Rough River Lake across ten sites by electrofishing in the spring of 2023. Fifty of the fin clips were randomly sent for genetic testing. Each fish that was chosen for testing was weighed, measured, and its otoliths were collected for age and growth analysis at a later date.

On average, Largemouth Bass alleles accounted for 85.5% of the total Largemouth Bass and Florida Bass alleles, so the population at Rough River Lake is slightly introgressed. Only one of the 50 fish collected would be considered a pure Largemouth Bass, while 7 had a Florida Bass allele percentage of more than 20%.

- Items of note about Rough River Lake: Rough River Lake is a 4,698-acre USACE flood control reservoir located in Breckinridge and Grayson counties. Genetic samples were taken on Rough River Lake in 1988, 1991, and 2005. In the 1988 and 1991 samples, Rough River Lake had a high variation of Largemouth Bass alleles and was found to be the most genetically diverse population of the samples taken. The population of Rough River Lake at that time was found to be 85% Largemouth Bass and 15% Florida Bass. In the 2005 results, Rough River had 90-92% Largemouth Bass alleles and 8-10% of Florida Bass alleles. The 2023 results show that the average Largemouth Bass alleles are 85.5% (14.5% Florida Bass alleles). The accuracy of the testing and number of loci evaluated have increased over time, but the most recent genetic results show little change from the previous genetic samples taken in 1988. This and the relatively low variance in the sample suggests that the introduction of Florida Bass genetics occurred prior to 1988 and possibly much longer ago. The department has never stocked Largemouth Bass in Rough River Lake.

Nolin River Lake: A total of 149 fin clips were taken from Nolin River Lake bass by electrofishing across 10 sites in the spring of 2023. At each location, Largemouth Bass were chosen at random for genetic sampling. Fifty of the clips were randomly sent for genetic testing; however, only 49 samples had usable results. Sagittal otoliths from each fish were collected for age and growth analysis at a later date.

On average, Largemouth Bass alleles accounted for 97.5% of the total Largemouth Bass and Florida Bass alleles, making Nolin River Lake the purest Largemouth Bass population tested. Only 5 of the 50 fish collected had a Florida Bass allele percentage greater than 5%.

- Items of note about Nolin River Lake: Nolin River Lake is a 5,596-acre USACE flood control reservoir located in Grayson, Edmonson, and Hart counties. Based on the results from Rough River Lake, the results for Nolin River Lake are slightly surprising. Rough River Lake is just 30 miles north of Nolin River Lake. It may be appropriate to use the data from Rough River Lake and compare it to the data of Nolin River Lake to potentially compare growth and fitness between a mixed genetic population and a population with pure Largemouth Bass. The department has never stocked Nolin River Lake with Largemouth Bass.

Lake Malone: In the fall of 2022 a total of 50 fin clips across 5 sites were collected by electrofishing from Lake Malone. At each location, Largemouth Bass were chosen at random for genetic sampling.

On average, Largemouth Bass alleles accounted for 93.5% of the total Largemouth Bass and Florida Bass alleles. Only 4 of the 50 fish collected had a Florida Bass allele percentage over 10%.

- Items of note about Lake Malone: Lake Malone was a private, 767-acre lake impounded by Mr. William C. Malone in 1961. Since then, the lake has been owned by the Kentucky Department of Fish and Wildlife Resources. Lake Malone was previously genetically tested in 2005. In the 2005 study, Lake Malone expressed 94-100% Largemouth Bass genetics, suggesting little change in the population since that time. Lake Malone has never been stocked with Largemouth Bass.

Western Fisheries District

Kentucky Lake: Fifty Largemouth Bass were randomly collected by electrofishing from our standardized electrofishing sample sites in the fall of 2022. Individual lengths and weights were also recorded so that they could be matched with genotypes.

On average, Largemouth Bass alleles accounted for 91.9% of the total Largemouth Bass and Florida Bass alleles. Only 15 of the 50 fish had a Florida Bass allele percentage over 10%, and only four had a Florida Bass allele percentage greater than 15%.

- Items of note about Kentucky Lake: Kentucky Lake is a 57,101-acre TVA flood control reservoir located in Marshall, Calloway, Lyon, Livingston and Trigg counties. The Tennessee side of Kentucky Lake has received several Florida Bass stockings from the Tennessee Wildlife Resources Agency (TWRA). From 1998-2004, Kentucky Lake received 40,000 Florida Bass per year. In 2015, a new Florida Bass stocking program began and has continued until present with roughly 300,000 bass stocked annually by their department. Beginning in 2020, TWRA authorized the stocking of additional Florida Bass by private entities and local county governments into areas of Kentucky Lake adjacent to the border with Kentucky. Bass in the Tennessee portion of the reservoir were genetically tested during 2015 to establish a baseline genetic profile prior to stocking. Their testing showed 83.7% Largemouth Bass and 16.3% Florida Bass alleles in their sample (Hargrove et al. 2019). These results were not surprising given the lake's stocking history, but when coupled with our results they suggest a gradient of Florida Bass alleles in the reservoir with more Florida alleles in the southern portion of the reservoir. Kentucky Lake has only been stocked by the KDFWR in 1992 and 2017.

Lake Beshear: Genetic sampling took place in fall of 2022 and spring of 2023. Although samples were originally collected in the fall of 2022, it was decided that collecting samples in spring of 2023 would be more useful since those spring fish were also aged using otoliths. Fish were collected from all around the lake by electrofishing and 50 samples were randomly selected for testing. Otoliths were collected from each fish so that age and growth could be assigned at a later date.

On average, Largemouth Bass alleles accounted for 97.0% of the total Largemouth Bass and Florida Bass alleles, so the population at Lake Beshear is one of the purest in the state. Of the 50 fish tested, only 8 had a Florida Bass allele percentage over 5%.

- Items of note about Lake Beshear: Lake Beshear is a 784-acre reservoir located in Caldwell and Christian counties. Lake Beshear is one of the best trophy bass lakes in the state and routinely produces Largemouth Bass over 8 pounds. Lake Beshear has only been stocked with Largemouth bass in 1962 and 1964.

Lake Barkley: Fifty fish were randomly selected by electrofishing from our standardized sampling embayments in the upper, middle, and lower lake sections in the fall of 2022.

On average, Largemouth Bass alleles accounted for 94.7% of the total Largemouth Bass and Florida Bass alleles. This population is among the purest in the state.

- Items of note about Lake Barkley: Lake Barkley is a 41,800-acre USACE flood control reservoir located in Trigg, Lyon and Livingston counties. Lake Barkley is connected to Kentucky Lake by a

canal which allows natural migration of fish. Additionally, anglers routinely travel between lakes during tournaments leading to an unknown amount of fish movement by anglers. However, our testing results suggest that these are two distinct populations and that Lake Barkley bass have much less Florida Bass introgression. Our results are very similar to TWRA's testing in their portion of Lake Barkley in 2015 which found that Lake Barkley bass contained 93.4% Largemouth Bass alleles and 6.6% Florida Bass alleles. The only Largemouth Bass stockings in Lake Barkley occurred in 1972 and 1978.

Appendix A

The raw data contains a lot of information and can be difficult to comprehend, but is available in Appendix A. The lake names are provided as well as the individual sample number, the contig ID's for each loci, the total genotype percentages, and the lengths and weights for each fish. Under each contig ID there should be a read for two alleles. Allele type 1 is the Largemouth Bass genotype, allele type 2 is the Florida Bass genotype. Any loci with a zero as a result represents a locus which did not produce readable results. Samples which did not produce any readable results at any loci are still listed but with zeros in each results column.

Many of the fish in these samples had their sagittal otoliths removed so that we could determine their age and growth rates. Those structures have not yet been examined but may yield some interesting results when coupled with the genetic information.

Appendix B

These data are simply a summary of the pertinent information available in appendix A. The contig ID's have been removed to create a more readable result.
