# WESTERN FISHERY DISTRICT 

Project 1: Lake and Tailwater Fishery Surveys

## FINDINGS

Sampling conditions for each survey event are listed in Table 1.

## Kentucky Lake

During the spring, 547 black bass were collected by diurnal electrofishing ( 120 PPS, DC current). During this sampling period, 467 largemouth bass ( 62.3 fish $/ \mathrm{hr}$ ) were collected from Blood River, Jonathan Creek, and Big Bear (Table 2). The catch rate (fish/hr) for largemouth bass was highest in Big Bear ( 80.8 fish $/ \mathrm{hr}$ ). Unlike previous years, Sugar Bay was not sampled. This was done to avoid interference with the ongoing snorkel surveys of the bass spawning habitat in that embayment.

The spring bass data was used to complete the lake specific assessment (Table 3). The lake specific assessment suggests that the largemouth bass population rated "Fair". The catch rate of age-1 largemouth bass in the sample was excellent indicating a good spawn in 2020. This is extremely encouraging as the two prior spawns were very poor. Our habitat plan is focused on increasing recruitment of largemouth bass in the reservoir, and we are hopeful that improving habitat can help the bass population to recover.

The size structure parameters used to assess the fishery by standards set in the Kentucky Lake Fish Management Plan (KLFMP) showed an above average catch of $<8.0$-in bass (Table 4). The catch rate of intermediate-size bass (12.0-14.9 in; 10.4 fish $/ \mathrm{hr}$ ) was well below the plan recommendation. The lower numbers of intermediate-size bass were expected due to the weak year classes of 2018 and 2019. The catch rate of harvestable-size bass ( $\geq 15.0 \mathrm{in}$ ) increased from the previous years' data, but still falls below the plan recommendation. The catch rate of trophy-size largemouth bass ( $\geq 20.0 \mathrm{in}$ ) was also below the average for the last 10 years and was below the KLFMP recommendation. The dominant size group of adult largemouth was around 15.0 in which was expected based on the strong year class in 2016 (Table 2).

Proportional Size Distributions (PSD) values were calculated for black bass collected from each embayment sampled during the spring (Table 5). The average PSD and $\mathrm{RSD}_{15}$ values for largemouth bass were 72 and 38, respectively. These average values were used in the KLFMP assessment. The PSD value is within the assessment preferred range (55-75; Table 4). The $\mathrm{RSD}_{15}$ value was 38 , which also falls inside the targeted range $\left(\mathrm{RSD}_{15}\right.$ of 2040).

During October, 470 black bass were collected by diurnal electrofishing ( 120 PPS, DC current) from four embayments; Blood River, Jonathan Creek, Big Bear, and Sugar Bay (Table 6). Largemouth bass comprised 52\% ( $61.3 \mathrm{fish} / \mathrm{hr}$ ) of this sample in Blood River and Jonathan Creek. Smallmouth bass comprised 47/\% ( $55.3 \mathrm{fish} / \mathrm{hr}$ ) of the 2021 sample for those two embayments and once again outnumbered the largemouth in Blood River. Based on length frequency it appears that most of those smallmouth were young-of-year, although the adult densities are starting to increase as well.

Length and weight data were recorded from all bass collected during the fall sample to calculate relative weight values. The mean relative weight for harvestable-size largemouth bass was 94 (Table 7). This value was down from the 2020 estimated relative weight value of 95 and is just outside the preferred range of $95-105$. The relative weight of largemouth bass is one parameter that is being watched as an indicator of the effects of the population of silver and bighead carp in the lake. As silver and bighead carp numbers continue to increase, they could impact the plankton levels and hence the upper levels of the food chain.

Length-weight equations for black bass species at Kentucky Lake are:
Largemouth bass $\log _{10}($ weight $)=-3.46692+3.12957 \times \log _{10}$ (length)
Smallmouth bass $\quad \log _{10}($ weight $)=-3.41613+3.05390 \times \log _{10}$ (length)

Otoliths were collected from a subsample of smallmouth bass and largemouth bass ( $<10.0 \mathrm{in}$ ) during fall sampling in 2021. Otoliths were used to age bass so that the catch rate and growth of age-0 fish could be evaluated. The catch rates of age- 0 smallmouth and largemouth bass during the fall sample were 49.7 and 47.3 fish $/ \mathrm{hr}$, respectively (Tables 8 and 9). The 2021 year class appears to be average, with below average growth. The mean length of the age- 0 largemouth bass was 4.4 in at time of capture in the fall. The catch rate of age- 0 largemouth bass $>5.0$ in was 17.6 fish/hr.

During 2020, largemouth bass age and growth data was collected in the fall. This age and growth data was coupled with fall 2021 data to yield an estimate of the age distribution for largemouth bass. Catch rates for fall-caught fish by age-class are shown in Table 10. Ages ranged from 0-9 with age-0 being the most abundant.

Because of a string of several weak bass spawns, WFD started placing bass spawning habitat in Kentucky Lake and Lake Barkley prior to the bass spawn in spring 2019. Habitat consisted of shallow-water laydowns (sometimes referred to as spawning benches) and artificial spawning beds. Artificial beds are bowl-shaped structures that provide preferred substrate for bass. Our artificial beds were initially constructed with plastic sides but we have since changed to using all concrete. Habitat was placed at water elevations slightly below winter pool in areas that were perceived as lacking good habitat. Our goal is to provide sufficient habitat at lower water elevations because it is possible that bass are sometimes ready to spawn before water is high enough to reach good shoreline habitat in the spring. A reduction in competition for habitat resources could lead to higher individual nest success. To help determine how fish use these structures we conducted 12 weekly snorkel surveys from March 24 - June 9, 2021, at Sugar Bay on Kentucky Lake (Table 11). We rated the relative amount of observed eggs and fry at 68 sites and collected egg and fry samples to help with identification. An additional rating of "cleaned off" was added to track beds that had been brushed clean of debris but had no eggs or fry. Summary percentages of usage are in Tables 12 and 13 .

In $2021,47 \%$ of the sites were used at least once by spawning bass including $3 \%$ of sites that were used twice by bass. $63 \%$ of artificial beds next to laydowns were used by bass, while artificial beds without laydowns were used at a rate of $44 \%$. The usage rates of laydowns without artificial nests were lower at $33 \%$. Once water temperatures started to warm up closer to 70 F , sunfish started to use our spawning habitat heavily. About $78 \%$ of our experimental habitat sites were used at least once by sunfish, and $94 \%$ of the artificial spawning beds were used by sunfish. Usage rates in 2021 were very similar to rates in 2020 but were consistently a few percentage points lower in 2021 (Table 14).

Across 68 sites in Sugar Bay, we suspect 34 individual bass spawning events occurred based on weekly snorkel surveys. During the spawn of 2021 we had 366 artificial beds and 195 laydowns deployed in Kentucky Lake and 268 artificial beds and 378 laydowns in Lake Barkley. Based on snorkel survey results, we determined the rate at which bass spawned at three different site types (artificial bed with an adjacent laydown; artificial bed only; and laydown only) in 2021. These rates differ slightly from usage rates because some sites produced multiple spawning events. If we assume identical rates across both lakes, we can extrapolate those numbers and estimate that bass spawned 460 times on our habitat in the spring of 2021. A typical bass nest may contain anywhere from 2,000-7,000 fry after hatch (Post et al., 1998) meaning our spawning habitat could have helped with the spawn of anywhere from about $920,000-3,220,000$ bass fry. It is possible however that bass would have spawned in these areas even without any artificial spawning habitat. This makes it very difficult to estimate the amount of additional bass fry produced because of our spawning habitat. During snorkel surveys we rarely noted any natural beds away from our habitat, but visibility often made that very difficult.

In order to further understand the timing and duration of the bass spawn, shoreline seining was conducted in Sugar Bay on June 29, 2021, and in Blood River on June 22, 2021. A 50 -foot seine with $1 / 4$-in mesh was used to collect YOY largemouth bass until a total of 100 specimens were collected from each embayment. Smallmouth bass were also collected from both embayments but were tough to find in Blood River. Each bass was measured for total length in mm and the sagittal otoliths were removed. Otoliths were mounted convex side up using thermoplastic cement, sanded with 1200 grit sandpaper, and polished with 0.3 -micron alumina powder.

Each otolith was aged independently by two readers using a compound microscope at $100 \mathrm{x}-400 \mathrm{x}$ magnification. Reader agreement was typically within 1-3 days, but if the difference between readers was less than $10 \%$ of the fish's estimated age, the counts were averaged and accepted. To determine hatch dates we used the equation
[(ordinal date collected)-(average ring count)-5)] (Dicenzo and Bettoli, 1995). To determine what dates bass were actually spawned on (when spawning activity took place on the nest), we used the equation [(hatch date)-3] (Heidinger, 1976). The results of the hatch date and spawn date analysis are provided in Tables 15 and 16.

Differences in spawn dates between species and embayments were initially compared with an F-test for variances. Then, depending on equal or unequal variance, the spawn dates were compared using appropriate T-tests. In 2021, the average largemouth bass spawn date in Sugar Bay (April $19 \pm 1.4$ days) was significantly earlier than in Blood River (April $25 \pm 1.4$ days; $\mathrm{p}=6.01 \mathrm{e}^{-9}$ ). This is the second year in a row that largemouth bass in Sugar Bay spawned earlier than largemouth bass in Blood River, which supports the theory that fish might spawn earlier in bays with our experimental spawning habitat if there is sufficient spawning habitat at lower water elevations. The average smallmouth bass spawn date in Sugar Bay (April $22 \pm 1.1$ days) was also significantly earlier than in Blood River (May $5 \pm 2.2$ days; $\mathrm{p}=4.54 \mathrm{e}^{-16}$ ). When both embayments were combined, the average smallmouth bass spawn date (April $27 \pm 1.4$ days days) was significantly later than the average largemouth bass spawn date (April $22 \pm 1.1$ days; $\mathrm{p}=3.15 \mathrm{e}^{-8}$ ). In 2020 this trend was the opposite.

Trap nets were fished for crappie in Blood River and Jonathan Creek embayments for 80 net-nights (nn) during October and November. In addition, Sledd Creek was sampled for 40 nn . This is the first time in recent history that Ledbetter Bay has been sampled for crappie. Otoliths were collected from a subsample of the entire population and used to assign ages and calculate mean lengths at age. The combined sampling effort yielded 1024 crappie ( 8.5 fish $/ \mathrm{nn}$ ), of which 5.2 fish $/ \mathrm{nn}(61 \%)$ were white crappie and $3.3 \mathrm{fish} / \mathrm{nn}(39 \%)$ were black crappie (Table 17). The Blood River and Jonathan Creek data are listed as "sub-total" on this table and only data from these two embayments were used in the proceeding assessments. The total catch rate of crappie $>$ age -0 was 4.9 fish $/ \mathrm{nn}$ which is below the goal of $20.0 \mathrm{fish} / \mathrm{nn}$ set in the KLFMP (Table 18). The low total catch rate reflects the weak spawns in 2016 and 2017. However, the catch rate of 5.1 fish/nn for age- 0 white crappie this fall was the highest catch rate we've seen since 2010.

The number of crappie $\geq 8.0$ in and $\geq 10.0$ in collected in trap nets was 2.9 and 1.1 fish $/ \mathrm{nn}$, respectively (Table 18). The KLFMP objective for crappie is to maintain a catch rate of at least 10.0 fish/nn for crappie $\geq 8.0 \mathrm{in}$, and 4.0 fish/nn for crappie $\geq 10.0 \mathrm{in}$. Neither objective was met this year.

Crappie at Kentucky Lake had slightly below average growth rates in 2021. The growth management objective in the KLFMP is for age- 2 crappie collected in the fall to reach 9.5 inches in length. The average length of the age- 2 crappie collected this year was 8.8 in (Table 18).

Another management objective in the KLFMP is to maintain a catch rate of age-1 crappie of at least 11.0 fish $/ \mathrm{nn}$ (Table 18). The catch rate for this age group of crappie was 1.5 fish $/ \mathrm{nn}$. This is on par with the lowest catch rates we have ever observed and indicates a very weak spawn in 2020. Interestingly and perhaps unfortunately, weak crappie spawns are typically associated with strong largemouth bass spawns (Table 4 and Table 18). For a discussion of the potential effects of environmental factors on the spawn, please refer to the 2017 Annual Performance Report.

These parameters are also used as part of the calculation for ranking the crappie fishery at Kentucky Lake. Overall, the crappie population at Kentucky Lake rated "fair" this year (Table 19).

The fall trap netting data was used to calculate proportional size distributions and length-weight equations for crappie. PSD and $\mathrm{RSD}_{10}$ values are reported in Table 20.

The mean relative weights of keeper-size ( $>10.0 \mathrm{in}$ ) white crappie and black crappie were (91) and (87), respectively (Table 21). These relative weights are much lower than we would like to see. However, we have had several comments from anglers about the good health of the fish. This is in stark contrast to 2017 when skinny crappie were a major source of complaints and concerns. Relative weights for white and black crappie in 2017 were (89) and (85), respectively, which is very similar to the relative weights in 2021. It was our observation in 2017 that the longest white crappie $(14+\mathrm{in})$ were the most emaciated. It is our belief that those extremely skinny large fish were the most concerning for our anglers.

Length-weight equations for white and black crappie are listed below.

$$
\begin{array}{ll}
\text { White crappie } & \log _{10}(\text { weight })=-3.63417+3.27130 \times \log _{10} \text { (length) } \\
\text { Black crappie } & \log _{10}(\text { weight })=-3.50899+3.20996 \times \log _{10} \text { (length) }
\end{array}
$$

Tables 22-27 list the back-calculated lengths at age for all white crappie, all male white crappie, all female white crappie, all black crappie, all male black crappie, and all female black crappie, respectively. Differences in growth rates between sexes were not obvious for either species. The age frequencies for white and black crappie collected are listed in Tables 28 and 29, respectively. The poor white crappie spawns reported in 2016 and 2017 are once again very noticeable as no 4- or 5-year-old white crappie were collected in 2021.

During the spring of 2021, icthyoplankton sampling was conducted in the Jonathan Creek embayment of Kentucky Lake. Weekly sampling began April 8, 2021 and ran through June 9, 2021. Samples were conducted using a rectangular neuston net with a 100 -micron mesh size, towed 50 feet behind a boat, at a speed of 1.5 mph . Tow duration was either 5 or 3 minutes depending on an a priori assessment of the expected concentration of icthyoplankton and leptodora to prevent clogging. A General Oceanics flowmeter was attached inside the mouth of the net to record the volume of water sampled during each run. Sampling began just after dusk and always followed the same site order. Each sampling event started closest to the main lake site and then progressed farther into the embayment (Appendix A).

Ichthyoplankton samples were preserved immediately in $95 \%$ ethanol and stored in mason jars. All larval fish were sorted and identified to the lowest practical taxon using "A Practical Key to Identify Families, Genera, and Species of Fish Larvae Commonly Collected in Tennessee Reservoirs" (Sammons, 1999), "Preliminary Guide to the Identification of Larval Fishes in the Tennessee River" (TVA, 1976), and "Early Development of Four Cyprinids Native to the Yangtze River, China" (Chapman, and Wang, 2006; Bolu Yi, et al. 1988). Once identified, fish were counted and measured for total length. In cases of more than 100 individuals in a sample, a random subsample of at least 30 individuals was measured and used to extrapolate the lengths of the fish from the entire sample. Larval crappies were not identified to species due to overlapping myomere counts between both species and their hybrids (Spier and Ackerson, 2004).

The geometric mean and median of the 6 sample sites were used to evaluate overall densities during each week (Table 30). The standard error and coefficients of variation of the mean and geometric mean were used to evaluate sample accuracy. In 2021 the peak weekly density of crappie occurred on June 3 rd and was 84.8 crappie $/ 1000 \mathrm{~m}^{3}$. This peak density occurred the latest in the year but was also the second highest since 2015 (Table 32). Based on these results, the crappie spawn in Jonathan Creek in 2021 appears to have been average or above average. This will still need to be verified by trap netting age-1 crappie in 2022. After tracking the crappie spawn since 2015 using ichthyoplankton nets, we have noticed a trend that the peak crappie catch rate in the spring is a good predictor of age 0 catch rates in fall trapnets (Regression $\mathrm{R}^{2}=0.94, \mathrm{p}<0.001$; Figure 1) and age 1 catch rates in trapnets the following fall $\left(R^{2}=0.88, p=0.005\right.$; Figure 2).

In order to determine the hatch dates of crappie more precisely, based on growth rates, all crappie that were 7-12 mm in total length were assumed to represent a one-week cohort (Table 31). Crappie in this size range appeared to be fully recruited to the gear and were best represented in the sample. It is possible that crappie shorter than 7 mm were not located in the pelagic sample sites yet, and that crappie over 12 mm were more likely to avoid capture. This length range was also chosen because a 7 mm crappie would grow to 12.1 mm in one week (our sample interval), based on a growth rate of 0.90 mm per day after swim up. This was our estimated daily growth rate from daily otolith ring counts of Jonathan Creek crappie collected later in the year (next section).

In addition to weekly cohorts, we also estimated daily cohorts of hatched crappie. All crappie that were captured outside of the $7-12 \mathrm{~mm}$ length range were excluded from the hatch date analysis to minimize the effects of gear bias and the longer exposure to natural mortality of older fish (Table 33). A hatch date was then back-calculated for each individual fish using the assumed growth rate ( $0.90 \mathrm{~mm} /$ day $)$ and the total length of each fish. A total length at hatch $(4 \mathrm{~mm})$ was factored into the regression for hatch date. This technique has been employed in other systems (Mitzner 1991). An incubation period of 95 hours (based on temperature) was also factored into the regression so that the day when fertilization occurred could be estimated.

The estimated hatching densities indicated that the spawn in Jonathan Creek lasted at least 47 days and extended at least until late May (Table 33). Because of our limited larval sampling window, we cannot be sure that crappie did not spawn after our sampling window. The literature reports most crappie spawns to be relatively short (1-2 months; Mitzner 1991 and Travnichek, et. al.1996). There seems to have been one strong peak in spawning activity in 2021 along with a few lesser peaks. The highest amount of spawning occurred from May 18 to May 21. Similar to prior years' surveys we found higher densities of larval crappie farther into the embayment (Table 30; Appendix A).

In July 2021 an effort was made to capture YOY crappie using a benthic otter trawl. Crappie were identified to species using dorsal fin counts, and a subsample of otoliths was collected from approximately 200 crappie for daily ring count analysis. The subsample was collected randomly without regard to crappie species or size. Crappie trawling has typically been conducted in the fall to assess year class strength. However, an earlier sample was necessary for accurate daily ring counts since those counts can become unreliable in fish $>100$ days old (Sweatman and Kohler, 1991). Trawling runs were conducted in Jonathan Creek because this is where the larval sampling occurred during the spring. To evaluate whether hatching periods and growth rates differed by embayment, trawling was also conducted at Blood River embayment. Otoliths were mounted convex side up using thermoplastic cement, sanded with 1200 grit sandpaper, and polished with 0.3 -micron alumina powder.

Each otolith was aged independently by two readers using a compound microscope at $100 \mathrm{x}-400 \mathrm{x}$ magnification. Reader agreement was typically within 1-4 days, but if the difference between readers was less than $10 \%$ of the fish's estimated age, the counts were averaged and accepted. In 2021, no fish were excluded based on reader disagreement. We were able to estimate an average daily growth rate for both species of crappie by using the equation described by Sweatman and Kohler (1991) [(total length mm-4mm)/\#days old-4 days]. This growth rate estimate was coupled with the larval data to provide an accurate estimate of crappie hatch dates in Jonathan Creek as described earlier (Table 33). There is no way to practically differentiate between crappie species in the larval samples. Therefore, the estimated growth rate used in the larval hatch date back calculation combined both species together. Our estimated growth rate of $0.90 \mathrm{~mm} /$ day was higher than the $0.67-0.71 \mathrm{~mm} /$ day we've seen the past few years.

Because the collection of black crappie was so low ( $n=2$ of 201; Table 34), both black and white crappie were combined when making comparisons across embayments. Differences in growth rates and hatch dates between embayments were initially compared with an F-test for variances. Then, depending on equal or unequal variance, comparisons were made using appropriate T-tests. In 2021, crappie in Blood River had a faster average growth rate ( $0.93 \mathrm{~mm} /$ day) than crappie in Johnathan Creek ( $0.90 \mathrm{~mm} /$ day; $\mathrm{p}=0.01$ ). Additionally, the average crappie hatch date in Johnathan Creek (May $19 \pm 1.0$ days) was not significantly different than in Blood River (May $20 \pm 1.2$ days; $\mathrm{p}=0.42$ ).

The catfish population was sampled at Kentucky Lake during June by using low pulse ( 15 PPS) electrofishing along the main lake river channel. A chase boat was utilized to help collect catfish around the electrofishing boat. One dipper was used in each boat. A total of 162 catfish were collected during 60 electrofishing runs (Table 35). Each run lasted 300 seconds, for a total sample time of 5.0 hours over a three-day period. Of the catfish species, blue catfish had the highest catch rate at 25.3 fish $/ \mathrm{hr}$, and made up $75 \%$ of the catfish collected. The catch rate was lower than observed in some previous years, but consistent with the last four years' results. Relative weight values are listed in Table 36. The relative weight values are all high, suggesting the fish are healthy.

## Lake Barkley

Black bass were collected during 9.0 hours of diurnal electrofishing (120 PPS, DC current) during the spring at sampling sites historically used on Lake Barkley. A total of 671 black bass were collected at a rate of 74.6 fish $/ \mathrm{hr}$ (Table 37). Spotted and smallmouth bass combined for about $7 \%$ of the total black bass sampled. The catch rate of small ( $\leq 8.0 \mathrm{in} ; 35.7 \mathrm{fish} / \mathrm{hr}$ ) largemouth bass was its highest since 2009, while catches of intermediate-sized (8.011.9 in) largemouth bass were about equal to the current ten-year average. The catch rates of large ( $\geq 15.0 \mathrm{in}$ ) and larger ( $\geq 18.0 \mathrm{in}$ ) largemouth bass continues to be below the average historic catch rate for these size groups. Several below-average spawns from 2014-2019 on Lake Barkley resulted in weak catch rates of age- 1 fish following those spawns and have likely reduced the overall numbers of large bass currently in the system. However, in 2021 the recruitment of largemouth bass (catch rate of age-1 fish in the spring; 41.7 fish $/ \mathrm{hr}$ ) was the 5th highest it has been since 1997. The long-term average for age-1 largemouth in the spring is about $25.0 \mathrm{fish} / \mathrm{hr}$, so we are optimistic that this strong 2020 cohort will provide a boost to the larger size classes of fish in the coming years. The overall largemouth bass catch rate was $69.1 \mathrm{fish} / \mathrm{hr}$ which is just above the average of the past ten years (Table 38). The overall smallmouth bass catch rate was 5.0 fish/hr which is the highest since 2005 which is when smallmouth bass started getting consistently collected at the same time as largemouth bass at Lake Barkley.

The overall PSD and $\operatorname{RSD}_{15}$ values for largemouth bass at Lake Barkley, along with values for individual embayments are listed in Table 39. The PSD value (72) is within the objective goal (PSD of 55-75) established in the Barkley Lake Fish Management Plan (BLFMP). This value indicates a balanced bass fishery. The RSD 15 (37) was also within the set goal (20-40). The spring catch rate of small ( $\leq 8.0 \mathrm{in}$ ) largemouth bass was above average while catches of medium ( $8.0-14.9 \mathrm{in}$ ) and larger ( $\geq 15.0 \mathrm{in}$ ) largemouth bass remain below the historical averages (Table 38).

The lake specific assessment score for Lake Barkley was "fair" (Table 40). The score was "fair" or "poor" for most of the last decade. Seasonal flooding as well as the occasional drought may have affected sampling in some years which in turn negatively influenced the assessment score. However, spring catch rates of most size classes of largemouth bass have been below average during this time as well. The fishery showed improvement in these ratings
in 2017 and was rated as "good". However, generally low catch rates overall have since negatively affected the score. We calculated age-3 largemouth bass mean length at capture as outlined by Murphy and Willis (1996) in addition to the traditional method. This method uses a weighted average based on the age-length key and includes all sampled fish per age class. Although differences are slight, we do feel that this calculation more accurately describes this metric, as all spring-sampled bass are included in the calculation. The annual mortality of largemouth bass older than a year was $34 \%$ as determined using catch-curve regression of fall-caught largemouth (Table 40).

Black bass were sampled in October to collect length-weight data to assess condition factors and to determine the strength of the 2021 year-class. A total of 596 bass were collected from Little River, Eddy Creek, Taylor Bay, and Jakes Fork Bay with about $75 \%$ being largemouth bass (Table 41). For historical comparisons, only data from Little River and Eddy Creek were used in the standardized population parameters of Lake Barkley bass. Largemouth bass were caught at a rate of 62.5 fish $/ \mathrm{hr}$ which is well below the historical average going back to 1998 . The catch rate of small fish ( $<8.0 \mathrm{in}$ ) was slightly above the historical average and was the majority of the fall catch. Catch rates of intermediate and large-sized largemouth bass were all below their respective 10-year averages. Relative weights were determined for all bass, but few adult smallmouth bass were collected (Table 42). Relative weights for all size groups of largemouth bass were good this year. The relative weight for harvestable-size ( $\geq 15.0 \mathrm{in}$ ) largemouth bass from Little River and Eddy Creek was 100 which is equal to the average for Lake Barkley and within the acceptable range. The length-weight equations for black bass at Lake Barkley are:

$$
\begin{array}{ll}
\text { Largemouth Bass } & \log _{10}(\text { weight })=-3.507+3.2115 x \log _{10}(\text { length }) \\
\text { Smallmouth Bass } & \log _{10}(\text { weight })=-3.464+3.1174 x \log _{10}(\text { length })
\end{array}
$$

During 2019, largemouth bass age and growth data was collected in the fall. This age and growth data was coupled with fall 2021 data to yield an estimate of the age distribution for largemouth bass. Catch rates for fall-caught fish by age-class are shown in Table 43. Ages ranged from $0-11$ with age- 0 being the most abundant.

Mean length of the age- 0 cohort of largemouth bass was 5.1 in (Table 44). This is below the historical average (5.3 in) but meets our 5.0 -in goal. It has been suggested that bass which reach at least 5.0 in by the fall will have a better chance of survival during their first winter. This year's total catch rate of age-0 largemouth bass from Little River and Eddy Creek ( 47.5 fish $/ \mathrm{hr}$ ) was above the historical average ( 34.6 fish $/ \mathrm{hr}$ ), while this year's catch rate of age- 0 largemouth bass over 5.0 in ( 23.0 fish $/ \mathrm{hr}$ ) was equal to the average catch rate since 2001 . This year we again collected age- 0 length and catch data on smallmouth bass. Mean length of the age- 0 cohort of smallmouth bass was 4.5 in (Table 45). Total catch rate ( 24.5 fish $/ \mathrm{hr}$ ) and the catch rate of age- 0 smallmouth bass over $5.0 \mathrm{in}(6.5 \mathrm{fish} / \mathrm{hr})$ were both ranked $2^{\text {nd }}$ of the three years we've done this.

Taylor Bay and Jake Fork Bay were sampled for the first time in the fall of 2021 to begin assessing potential effects of artificial spawning habitat on black bass. As stated in the Kentucky Lake section, we have been placing this habitat as a result of some bad spawning events and overall low bass abundance recently. The additional spawning habitat at lower lake elevations in the test bays may provide more preferred areas for bass to spawn and areas for bass to spawn earlier in the year. Bass spawned earlier should, theoretically, be longer when sampled in the fall. Two of the metrics we're using to assess the effectiveness of artificial habitat are catch rate and average length of age-0 fish as compared to Little River and Eddy Bay, which both have no artificial habitat and are sampled every fall. The fall of 2021 was mostly a preliminary sample since there was only a small amount of artificial habitat in either test bay. The average length of age-0 largemouth bass was 4.8 in, slightly shorter than Little River and Eddy Bay ( 5.1 in ). Age-0 largemouth bass were caught at 90.0 fish/hr which is a much higher rate than Little River and Eddy Bay ( $47.5 \mathrm{fish} / \mathrm{hr}$ ). Age-0 largemouth bass over 5.0 in were also caught at a higher rate in test bays ( 35.5 fish $/ \mathrm{hr}$ vs $23.0 \mathrm{fish} / \mathrm{hr}$ ). Smallmouth bass were caught at lower rates overall but displayed the opposite trends. Age-0 smallmouth bass were longer on average in test bays ( 4.8 in vs 4.5 in ) and caught at higher rates ( $24.5 \mathrm{fish} / \mathrm{hr}$ vs 13.5 fish $/ \mathrm{hr}$ ) than Little River and Eddy Bay. It will be interesting to see if any trends develop in these bays after the addition of 179 artificial spawning beds and 219 laydowns in Taylor Bay and Jake Fork Bay in 2021 and early 2022.

Trap nets were fished for crappie in Little River and Donaldson Creek embayments for 80 net-nights (nn) during October and November. A total of 1640 crappie were collected at a rate of 20.5 fish $/ \mathrm{nn}$ (Table 46). Additionally, Crooked Creek (LBL) was sampled for another 40 net-nights. Crooked Creek ( 19.3 fish $/ \mathrm{nn}$ ) also provided a good sample and will remain on the sampling schedule in the future if possible.

White crappie accounted for $88 \%$ of the total catch and were caught at 17.6 fish $/ \mathrm{nn}$. Black crappie accounted for the remaining $12 \%$ of the total catch and were collected at a rate of 2.5 fish $/ \mathrm{nn}$ (Table 46). The mean relative weights for keeper-size ( $\geq 10.0$ in) black and white crappie were 98 and 100, respectively (Table 47). For historical comparisons, only data from Little River and Donaldson Creek were used in the standardized population parameters of Lake Barkley crappie in Table 48. The catch rate of harvestable-size ( $\geq 10.0 \mathrm{in}$ ) crappie was 0.8 fish $/ \mathrm{nn}$, which is lower than the ten-year average of 1.4 fish $/ \mathrm{nn}$. The catch rate of quality-size ( $\geq 8.0 \mathrm{in}$ ) crappie was 2.4 fish $/ \mathrm{nn}$, which is below the management objective ( 4.0 fish $/ \mathrm{nn}$ ) set in the BLFMP. The catch rate of age- 1 crappie ( $3.5 \mathrm{fish} / \mathrm{nn}$ ) was also below the management objective ( 5.0 fish $/ \mathrm{nn}$ ).

The length-weight equations of white and black crappie from Lake Barkley are:

$$
\begin{array}{ll}
\text { White crappie } & \log _{10}(\text { weight })=-3.831+3.5315 \times \log _{10} \text { (length) } \\
\text { Black crappie } & \log _{10}(\text { weight })=-3.341+3.5965 \times \log _{10} \text { (length) }
\end{array}
$$

Crappie collected in trap nets in Little River and Donaldson Creek were used to determine stock densities. The PSD (54) of white crappie was just below the historic average of 57 , while the $\operatorname{RSD}_{10}(18)$ of white crappie was also below the historic average of 27. These metrics suggest a somewhat balanced size distribution of white crappie that is missing some larger fish (Table 49). The PSD (59) of black crappie was slightly higher than the historic average of 55, while the $\operatorname{RSD}_{10}$ (17) of black crappie was slightly lower than the historic average of 20 . These metrics also suggest a somewhat balanced size distribution of black crappie that is missing some larger fish.

Otoliths from 386 crappie were used for age and growth analysis. Ages ranged from 0-7 years for white crappie and $0-3$ years for black crappie (Tables 50 and 51). Growth continues to be good as crappie generally reached 10.0 in between age 1 and 2 at capture. There did not appear to be any major differences in growth patterns between male and female white crappie (Tables 52 and 53) or black crappie (Tables 54 and 55). The average lengths of age- 2 white crappie and black crappie at capture were 11.1 in and 9.6 in, respectively (Table 56). In addition, we calculated age- 2 crappie mean length at capture as outlined by Murphy and Willis (1996) for all years presented in Table 56. This method uses a weighted average based on the age-length key and includes all sampled fish per age class. Although differences are slight, we do feel that this calculation more accurately describes this metric, as all crappie are included in the calculation.

Age frequencies were estimated by combining catch data with age data. $79 \%$ of white crappies captured in Little River and Donaldson Creek were age-0 fish while age-1 fish made up another $18 \%$ of the catch (Table 57). Few white crappies age- 2 and older were collected. $80 \%$ of black crappies captured in Little River and Donaldson Creek were age-0 fish while age- 1 fish made up another $10 \%$ of the catch. Few black crappies older than age- 2 were collected (Table 58). The age-0 white crappie catch rate was well above the long-term average in 2021 and was the $4^{\text {th }}$ highest on record back to 1985 . The age- 0 catch rate of black crappie was slightly higher than the long-term average. This preliminary age-0 data suggests that 2021 could have been a good crappie spawn.

Assessment of the crappie population yielded a rating of "Fair" at Lake Barkley in 2021 (Table 56) The catch of age- 1 crappie was below the ten-year average; however, catches of age- 0 fish were above average. The catch rate of crappie $\geq 8.0$ in continues to rise but is still below the ten-year average while the average length of age- 2 crappie is just slightly below the ten-year average. The catch rate of larger fish ( $\geq 8.0 \mathrm{in} ; 2.4$ fish $/ \mathrm{nn}$ ) was its highest in 5 years but still below the long-term average of 3.7 fish $/ \mathrm{nn}$. We are hopeful that the high catch of age- 0 white crappie this year will boost catch rates of larger fish in the next couple years.

The catfish population was sampled along the main lake river channel at Lake Barkley in June and July with lowpulse ( 15 PPS ) electrofishing while utilizing a chase boat to collect fish further away from the electrofishing boat. One dipper was always positioned in each boat for a total of two dippers. A total of 552 catfish were collected during 60 electrofishing runs (Table 59). Each run lasted 300 seconds, for a total sample time of 5.0 hours over a three-day period. Blue catfish had the highest catch rate at 101.4 fish/hr and made up $92 \%$ of the catfish collected. Flathead catfish and channel catfish are likely underrepresented using this method as these fish were often observed but were much harder to approach and dip than blue catfish. Relative weight values were all within or greater than ideal values of 95-105 and are listed in Table 60.

## Lake Barkley Creel Survey

A random, non-uniform probability, roving creel survey was conducted on the Kentucky portion (45,600 a) of Lake Barkley from 01 March to 30 November 2021. The Kentucky portion of the lake was divided into eight creel areas (Appendix B). The survey was conducted six hours per day, with the goal of 5 days per week. However, the clerk left the position before the end of the survey and WFD staff filled in for the final two months as time allowed. One hour each day was randomly chosen to conduct an angler count. The remaining five hours was dedicated to creeling anglers actively fishing. The overall temporal sampling scheme was twenty days per month, consisting of six weekend days and fourteen weekdays. Varying time period probabilities were assigned to each month. Higher geographic probabilities were assigned to the Eddy Creek and Little River areas in March, April, October, and November, resulting in more frequent interviews during months with historically less fishing effort. Equal probabilities were assigned to all areas from May to September. An angler attitude questionnaire concerning fishing on Lake Barkley was conducted by the creel clerk throughout the survey period (Appendix C).

During the 2021 creel, the typical angler was a male ( $85 \%$ ) resident ( $76 \%$ ) who was casting ( $42 \%$ ) or still fishing ( $51 \%$ ) from a boat ( $85 \%$; Table 61). Of the crappie anglers, $36 \%$ used a spider rig (defined as 3 or more poles per angler) for fishing. The average fishing trip for all anglers was 4.34 hours. There was a decline in the number of trips of $(40,898)$. This is the lowest number of trips ever recorded in a Lake Barkley creel survey and is less than half the number of trips from the 2018 survey. Anglers also caught a record low number of fish $(209,277)$. We suspect the original clerk may have been an inefficient user of his time on the water which could have led to lower overall effort and catch in this survey. Length frequencies of all harvested or released fish are given in Table 62.

Table 63 provides fish catch and harvest statistics for the 2021 creel survey. Crappie anglers accounted for $24 \%$ of fishing trips to Lake Barkley in 2021 ( $20 \%$ in 2018, $24 \%$ in 2016, $17 \%$ in 2012). Estimated catch and harvest rates for crappie were average to slightly below average. Crappie anglers caught 1.1 fish $/ \mathrm{hr}$ which is equal to the longterm average of 1.1 fish $/ \mathrm{hr}$. Of the crappie caught, $45 \%$ were a harvestable size (Table 64). This slightly higher proportion of sub-legal sized crappie corresponds to fall trap netting data that suggested two very poor spawns in 2016-2017 followed by slightly better spawns for the last three years. Forty-five percent of the crappie were caught in March-May (Table 65). As part of our efforts to evaluate harvest by method, crappie anglers were recorded as using the following methods: casting, still fishing (1-2 poles), spider rigging ( 3 poles), spider rigging ( $4-5$ poles), spider rigging ( $>5$ poles). During this survey, $36 \%$ of crappie anglers used 3 or more poles. The percentage of crappie anglers using ( $>5$ poles) decreased to $4 \%$ in 2021 compared to only $19 \%$ of crappie anglers in 2018 (Table 66). There is an ongoing trend in crappie fishing right now to use only one or two poles in conjunction with advanced live-imaging sonar to target individual fish. During 2021, about one quarter of crappie anglers consistently used live-imaging sonar, and it will be interesting to see if we are able to capture this rising trend in future creel surveys.

Black bass anglers accounted for $35 \%$ of all fishing trips to Lake Barkley during 2021 (Table 63). There were 14,109 black bass fishing trips in the 2021 creel. During older surveys, any bass that was currently in the livewell was recorded as harvested. However, during recent surveys, anglers with bass in the livewell were asked if they intended to release them at the end of the day. In all cases, tournament anglers indicated that they intended to release their fish after the weigh-in. Additionally, some non-tournament anglers simply chose to keep fish in the livewell for photographic or "mock tournament" purposes but indicated that they would release them at the end of the day. As a comparison with previous surveys, bass kept in livewells by anglers were reported as harvested, even though they would be released at the end of the day. The harvest rate, which included tournament bass and "mock tournament" bass, was estimated to be 0.06 bass per hour for anglers actually targeting bass (Table 67). However, when tournament and "mock tournament" harvested bass were removed from the actual harvest, the harvest rate dropped to 0.007 bass $/ \mathrm{hr}$. Largemouth bass accounted for $79 \%$ of the harvested black bass by number (Table 68).

About $8 \%$ of all trips were taken to catch panfish during 2021 (Table 63). This is approximately equal to the average percentage of panfish trips since 1999. Catch and harvest rates of panfish were below the long-term averages in 2021. Almost $80 \%$ of the panfish were harvested during May (Table 69). Bluegill and redear sunfish accounted for $100 \%$ of the panfish harvested. Of the bluegill, only $39 \%$ of the fish caught were harvested, while $44 \%$ of the redear sunfish caught were harvested (Table 70). Although fish are observed by the creel clerk whenever possible, it is possible that some percentage of misidentification took place by anglers when reporting panfish catch and release.

Catfish anglers accounted for $21 \%$ of all fishing trips on Lake Barkley in 2021 (Table 63). The number of trips for catfish was well below the long-term average. The catfish fishery remains highly harvest oriented. Almost $74 \%$ of the catfish caught were harvested (Table 71). The total catch of channel catfish was a few thousand fish greater than the total catch of blue catfish, while the total catch of flathead catfish was minimal (Table 72). Only $8 \%$ of catfish anglers reported that they considered catching trophy fish to be their goal, while $72 \%$ reported a goal to catch keeper sized fish to eat (Appendix C). Catching keepers has consistently been much more of a priority to catfish anglers since we started asking them this question several years ago.

Less than $2 \%$ of the anglers fishing Lake Barkley in 2021 sought Morones (Table 63). This group includes white bass, yellow bass, striped bass, and hybrids. However, it is likely that most anglers were fishing for white or yellow bass. Positive ID on this genus can be difficult for anglers, so it is possible that some released fish were misidentified. The highest total catches of Morones occurred in November and May in 2021 (Table 73). Approximately $62 \%$ of the Morones caught were yellow bass, with white bass making up the remaining $38 \%$. About $71 \%$ of yellow bass were released after being caught (Table 74).

An angler attitude survey was also given to anglers willing to participate (Appendix C). The opinions on the black bass fishing continue to worsen with $46 \%$ of anglers reporting that they were somewhat or very dissatisfied ( $30 \%$ in $2018,7 \%$ in 2016). Most dissatisfied black bass anglers are not happy with the number of fish caught. Just $43 \%$ of crappie anglers were in favor of pole limits while $57 \%$ were opposed or had no opinion. Only about one quarter of crappie fisherman used real time sonar while fishing. About $75 \%$ of catfish anglers would support a statewide 12inch minimum length on catfish. About $72 \%$ of catfish anglers believe catching more keepers is more important than catching trophies. The percentage of anglers ( $76 \%$ ) who stated they knew that Asian carp were widely considered to be a good fish to eat was higher in 2021 than recent surveys. Additionally, $87 \%$ of anglers were aware that commercial fishing for Asian carp was occurring on Lake Barkley. There was also a section of questions directed at tournament anglers. Although the sample size was lower than we would like ( $\mathrm{n}=60$ ) , $83 \%$ of the tournament anglers interviewed said they would be in favor of a free tournament permit system.

## Lake Beshear

Largemouth bass were collected by diurnal electrofishing (120 PPS, DC current) during April at Lake Beshear. Two-hundred-and-fifty-one largemouth bass were collected at a rate of 100.4 fish $/ \mathrm{hr}$ (Table 75). The catch rate of harvestable-size ( $\geq 12.0 \mathrm{in}$ ) largemouth bass was 45.2 fish/hr (Table 76). This year's sample falls just above the objective in the Lake Beshear Fish Management Plan (LBFMP) to maintain a catch rate of at least 45.0 fish $/ \mathrm{hr}$ for harvestable-size largemouth bass. The catch of age-1 fish was high this year ( 23.2 fish $/ \mathrm{hr}$ ). Other objectives are to maintain high catch rates of bass $\geq 15.0$ and $\geq 20.0 \mathrm{in}$. Ideally, these catch rates should be greater than 30.0 and 3.0 fish $/ \mathrm{hr}$, respectively. The catch rates per hour for these length groups of bass were 36.4 and 6.0 , respectively. Lake Beshear continues to have a quality bass fishery with good numbers of bass $\geq 15.0 \mathrm{in}$. However, the lower catch of bass 12.0-14.9 in this spring is a potential concern and may lead to some slight angler dissatisfaction in the future. The fishery rated as "good" in 2021 thanks in part to strong recruitment and solid numbers of trophy-size fish (Table 77).

Largemouth bass were also collected by diurnal electrofishing (120 PPS, DC current) in October (Table 75). The catch rate ( 156.4 fish $/ \mathrm{hr}$ ) was an improvement over last year, but again the catch was skewed towards smaller fish. Relative weight data (Table 78) suggests that larger bass ( $\geq 15.0 \mathrm{in}$ ) are healthy with regard to their length-weight ratio. The average relative weight value was 94 for these larger bass and 82 for all sizes of bass. However, the reduced body weights of the smaller fish are indicative of a lack of smaller forage and should be monitored closely to see if this trend continues. The length-weight equation for largemouth bass at Lake Beshear is:

$$
\log _{10}(\text { weight })=-3.52039+3.14135 \times \log _{10}(\text { length })
$$

Otoliths were removed from a subsample of largemouth bass $\leq 10.0$ in to determine the mean fall length of the age- 0 cohort and determine their catch rate. The catch rate for age-0 largemouth bass was 83.6 fish $/ \mathrm{hr}$ (Table 79). The average length of an age- 0 bass was 4.8 in.
The catfish population at Lake Beshear was sampled in June using trotlines and tandem hoopnets. A total of 131 channel catfish and 146 blue catfish were collected in the hoopnets for catch rates of 43.7 and $48.7 \mathrm{fish} / \mathrm{hr}$, respectively (Table 80). A total of 45 channel catfish and 60 blue catfish were collected on trotlines baited with cutbait (Table 81). The mean relative weights for channel catfish and blue catfish were 95 and 88 , respectively (Table 82). The lower blue catfish relative weights will be monitored again in 3 years to determine whether stocking rates need to be adjusted; however, the channel catfish relative weights support the appropriateness of the current stocking rates.

Otoliths were removed from a subsample of fish to assess growth rates and monitor for successful natural spawns (Tables 83 and 85). The catch was unsurprisingly dominated by two age classes from the most recent stockings; however, some older fish are reaching trophy sizes (Table 83). Growth rate of channel catfish has improved since changing the stocking schedule to a 2 -year rotation (Table 85). The mean length at age 3 from earlier channel catfish stockings was around 8.0 in , but the more recent stockings averaged around 13.0 in . Given the lack of significant natural reproduction, a mortality estimate was not appropriate. However, survival appears to be adequate based on the presence of older fish in the system (Tables 84 and 86).

## Lake Pennyrile

Electrofishing for all species of sportfish at Lake Pennyrile was conducted on May 7, 2021. Thirty-three largemouth bass were captured at a rate of 33.0 fish $/ \mathrm{hr}$ (Table 87). This catch rate is well below the 10 -year average of 90.6 fish/hr (Table 88). Most largemouth bass were still below 12.0 in. Only 2 ( $6.1 \%$ ) bass were 12.0 in or larger, while only $1(3.0 \%)$ bass was over 15.0 in from this year's sample. The catch rate of fish $\geq 15.0 \mathrm{in}(1.0 \mathrm{fish} / \mathrm{hr})$ is below the 10 -year average of $2.1 \mathrm{fish} / \mathrm{hr}$ (Table 88). The catch rate of largemouth bass 8.0-11.9 in was $18.0 \mathrm{fish} / \mathrm{hr}$ which is well below the management objective of 80.0 fish/hr. It appears we may have missed the bass with the timing of our sample this year. In previous years many more bass have been caught, and recently the bass have been stunted around 9.0-10.0 in. These high catch rates of intermediate-size largemouth bass are desirable in order to maintain good numbers of large sunfish in this system. The overall largemouth bass population was rated as "poor" in 2021 (Table 89). Due to the shift in management focus towards trophy sunfish, it is unlikely that the largemouth bass population will be rated highly again soon.

The catch rate of large-size ( $\geq 8.0 \mathrm{in}$ ) bluegill was above average at 22.0 fish $/ \mathrm{hr}$. (Table 90). This was our fourth highest catch of large bluegill on record. The catch rate of large ( $\geq 8.0 \mathrm{in}$ ) redear was below average at $13.0 \mathrm{fish} / \mathrm{hr}$. While the catch of redear $\geq 8.0$ in has been below average for the past three years, the catch of redear just below this length has increased in that time. We will continue to monitor the panfish populations at Lake Pennyrile in 2022.

PSD and RSD values for largemouth bass, bluegill and redear sunfish are listed in Table 91. The PSD value for largemouth bass (10) suggests a population heavily skewed toward small bass. The largemouth bass fishery is stunted which is our goal when managing for large panfish. The PSD value for bluegill (81) suggests a population skewed towards larger fish which coincides with our goals at this lake. The PSD value for redear (51) suggests a more balanced size distribution.

## Lake George

Electrofishing for all species of sportfish was conducted at Lake George (Marion, KY, Crittenden Co.) on May 11, 2021. Ninety-one largemouth bass were captured at a rate of 91.0 fish $/ \mathrm{hr}$ (Table 92). Catch rates of all size classes of largemouth bass were good (Table 93). The PSD and RSD values (Table 94) of largemouth bass suggest a fairly balanced population with a good number of larger individuals.

The catch rate of bluegill was 390.0 fish/hr (Table 92). The PSD (24) of bluegill suggests an unbalanced population skewed towards small fish (Table 94). The catch rate of redear sunfish was 111.0 fish $/ \mathrm{hr}$ (Table 92). The PSD (91) of redear suggests a population heavily skewed towards larger fish (Table 94). Black crappie, white crappie, and channel catfish were also collected but at much lower rates (Table 92).

## Lake Blythe

Electrofishing for all species of sportfish in Lake Blythe (Hopkinsville, KY, Christian Co.) was conducted on May 10, 2021. Catch rates of all sportfish were well below what they had been in the previous survey in 2019, and it is unclear what the cause for this is (Table 96). Due to only having 2 previous surveys on file for this lake, it is unknown if this has happened before. Sixteen largemouth bass were captured at a rate of 16.0 fish $/ \mathrm{hr}$ (Table 95). Of these 16 fish, 5 of them were greater than 18.0 inches in length.

The catch rate of bluegill was 47.0 fish $/ \mathrm{hr}$ (Table 95). The PSD (16) of bluegill suggests an unbalanced population skewed towards small fish (Table 97). The catch rate of redear sunfish was 19.0 fish/hr (Table 95). The PSD (26) of redear suggests an unbalanced population skewed towards small fish (Table 97). The catch rate of channel catfish was $14.0 \mathrm{fish} / \mathrm{hr}$ (Table 95). The PSD (100) of channel catfish suggests a population with a size distribution skewed towards large fish and minimal reproduction, if any (Table 97). The catch rates of white crappie and black crappie were minimal.

## Ballard County Wildlife Management Area Lakes

On May 13, 2021, several Ballard County Wildlife Management Area lakes (Butler, Shelby, and Castor) were sampled with electrofishing (2-900-second runs at each lake). These lakes are old oxbows of the Ohio River which are primarily managed for waterfowl. The fisheries in these systems fluctuate greatly due to the nearly annual connection with the river during flood events. Each of the lakes shows potential for good bluegill fishing, despite low numbers of bluegill $>6.0$ in (Table 98).

## Duncan Lake (LBL)

On May 17, 2021, Duncan Lake in the Land Between the Lakes National Recreation Area was sampled with electrofishing. Staff of LBL had contacted us wanting to know if we thought this lake could be promoted as a fishing opportunity. Very few fish were collected in almost 41 minutes of electrofishing (Table 99). The few largemouth bass that were collected appear stunted with all individuals under 12.0 in. Forage for bass was limited, as the catch rate of bluegill was also very low. The lake itself is heavily silted and shallow which may make any future management of the fish populations very difficult.

## USFWS Lakes

On May 14, 2021, two small USFWS lakes were sampled with electrofishing. The pond in Benton Kentucky is a small public fishing lake which we have sampled nearly annually for many years. The largemouth bass catch rate was $22.0 \mathrm{fish} / \mathrm{hr}$ which is concerning so it was supplementally stocked with 300 largemouth from our hatcheries during the fall (Table 100). The bluegill catch rate was 108.0 fish/hr, but the size distribution was skewed heavily towards smaller fish.

We also sampled a smaller pond which was newly acquired by the USFWS near Symsonia Kentucky. The catch rate of bass in this pond was only $6.0 \mathrm{fish} / \mathrm{hr}$ (Table 101). This pond was also supplemented with 350 largemouth bass from our hatcheries in the fall of 2021. The wide range of species is indicative of prior flooding and connection with the nearby river. However, the USFWS have made efforts to prevent future flooding. Both the Symsonia pond and the Benton pond are being managed for large sunfish and high catch rates of bass.

Table 1. 2021 yearly summary of sampling conditions by waterbody, species sampled, and date.

| Water body | Location | Species | Date | Effort | Gear | Weather | Water temp. ${ }^{\circ} \mathrm{F}$ | Water level | Secchi <br> (in) | Water conditions | Pertinent sampling comments |

Table 3. Lake specific assessment for largemouth bass collected at Kentucky Lake from 2012-2021. This table includes the parameter estimates and the individual scores as well as the total score and assessment rating. The final two columns list the instantaneous mortality $(Z)$ and \% annual mortality (A). Only data collected from Blood River, Big Bear, Jonathan Creek, and Sugar Bay were used for historical comparison.

Data from 1985 to 2011 is listed in previous annual reports.
Assessment quartiles were updated in 2015, previous years' APR's will list rating based on old assessment ranges.
**age and growth data was not collected this year, therefore used previous age data set estimates.
2013* samples were hampered by high water levels during flooding, sample was later than normal; overall a poor sample and not all embayments were sampled.

2012* sample was hampered by low water levels during drought.
*** mortality rates were calculated from fall caught and aged fish.
****Mean length calculated using a weighted average applied to the entire sample
Rating
5-7 = Poor (P)
8-11 = Fair (F)
12-16 = Good (G)
17-20 = Excellent (E)

Table 11. Lake conditions and spawning activity rating for each survey site during snorkel surveys in Sugar Bay, 2021. WFD laydowns were placed by KDFWR staff and Natural laydowns were pre-existing laydowns that were monitored. Rating 0-5 was based on relative density of observed eggs or fry, c=cleaned off (bed brushed clean of debris), blank=not found/not searched for. LMB=largemouth bass, SMB=smallmouth bass, BASS=undetermined black bass, SF=sunfish.

Table 15. Estimated hatch dates of largemouth bass in Sugar Bay and Blood River at Kentucky Lake, derived using daily ring counts of juveniles in 2021. "\# hatch" represents the time when bass actually hatched on the nest. "\#spawned" represents the estimated time when eggs were fertilized. Elevation (mean feet above sea level) and mean daily discharge (cubic feet/second) at Kentucky Dam also provided. Daily mean temperature readings ( 1 meter below surface) taken at Hancock Biological Station in main channel. Environmental variables were provided by TVA and Murray State University.

A Indicates year where age and grow th data $w$ as not collected. Age and grow th data from the previous year was used to calculate the appropriate value.
*Mean length calculated using a w eighted average applied to the entire fall trapnet sample
Data from 1985 to 2011 is listed in previous annual reports.
KLFMP - Kentucky Lake Fish Management Plan objective goal.
Kentucky Lake Crappie Database

Table 19. Lake specific assessment for crappie collected at Kentucky Lake (Blood River and Jonathan Creek) from 2012-2021. This table includes the individual scores for each parameter, as well as the total scores and assessment ratings. The final columns list the instantaneous mortality $(Z)$ and annual mortality $(A)$.

Table 33. Estimated crappie hatch dates in Jonathan Creek, derived using larval fish lengths back calculated using a growth rate derived from the daily ring counts of juveniles in 2021. Hatch dates from Jonathan Creek and Blood River derived solely from daily ring counts of juveniles also provided. "\# hatch" represents the time when crappie actually hatched on the nest. "\#spawned" represents the estimated time when crappie eggs were fertilized. Elevation (mean feet above sea level) and mean daily discharge (cubic feet/second) at Kentucky Dam also provided. Temperature readings (1 meter below surface) taken at Hancock Biological Station in main channel. Environmental variables were provided by TVA and Murray State University.

| Jonathan Creek |  |  |  |  | Blood River |  | Environmental variables |  |  |

Table 34. Estimated hatch dates of black and white crappie in Jonathan Creek and Blood River, derived using daily ring counts of juveniles in 2021. "\# hatch" represents the time when crappie actually hatched on the nest. Elevation (mean feet above sea level) and mean daily discharge (cubic feet/second) at Kentucky Dam also provided. Temperature readings (1 meter below surface) taken at Hancock Biological Station in main channel. Environmental variables were provided by TVA and Murray State University.

|  | Jonathan Creek |  | Blood River |  | Environmental variables |  |  |

Table 40. Lake specific assessment for largemouth bass collected at Lake Barkley from 2012-2021. This table includes the parameter estimates and the individual scores as well as the total scores and assessment ratings. The final two columns list the instantaneous mortality rate $(Z)$ and the annual mortality (A).

| Year | Mean length age-3 at capture | Mean length age-3 at capture*** | $\begin{aligned} & \text { CPUE } \\ & \text { age-1 } \end{aligned}$ | Length group |  |  | Total score | Assessment rating | Z | A |

## Appendix B. Lake Barkley Creel Survey Areas 2021.

## Appendix C. LAKE BARKLEY ANGLER ATTITUDE SURVEY 2021

1. Have you been surveyed this year? Yes - stop survey No - continue
2. Name $\qquad$ (Optional) and Zip Code $\qquad$
3. On average, how many times do you fish Lake Barkley in a year? $\mathrm{N}=227$

First time here $3.5 \% \quad 1$ to 4 13.2\% $5-10$ 11.9\% $\quad$ More than 10 71.4\%
4. Which species of fish do you fish for at Lake Barkley (check all that applies)? $\mathrm{N}=231$

Redear 4.8\% Bluegill 13.0\% Black Bass 57.6\% Crappie 48.5\% Catfish 41.6\% White bass 6.1\% Yellow bass $1.3 \%$ Other- Carp 0.4\%; Anything 0.9\%
5. Which one species do you fish for most at Lake Barkley (check only one)? $\mathrm{N}=231$ Redear 0.4\% Bluegill 3.5\% Black Bass 45.0\% Crappie 27.7\% Catfish 20.8\% White bass 1.3\% Yellow bass 0.4\% Other- Anything 0.9\%

## Answer the following questions for each species you fish for - (see question 4)

## Redear Anglers

6. In general, what level of satisfaction or dissatisfaction do you have with redear fishing at Lake Barkley? $\mathrm{N}=11$ Very satisfied 36.4\% Somewhat satisfied 18.2\% Neutral 27.3\% Somewhat dissatisfied 9.1\% Very dissatisfied 9.1\%

6a. If you responded with somewhat or very dissatisfied in question (6) - what is the single most important reason for your dissatisfaction? $\mathrm{N}=2$
Number of fish $50.0 \%$ Size of fish $0.0 \%$ Not happy with regulations $0.0 \%$ Don't know how to catch them $0.0 \%$ Asian carp 50.0\%

## Bluegill Anglers

7. In general, what level of satisfaction or dissatisfaction do you have with the bluegill fishing at Lake Barkley? $\mathrm{N}=30$ Very satisfied 16.7\% Somewhat satisfied 30.0\% Neutral 16.7\% Somewhat dissatisfied 16.7\%
Very dissatisfied 20.0\%
7a. If you responded with somewhat or very dissatisfied in question (7) - what is the single most important reason for your dissatisfaction? $\mathrm{N}=11$
Number of fish 90.9\% Size of fish 0.0\% Not happy with regulations 0.0\% Asian carp 9.1\%

## Black Bass Anglers

8. In general, what level of satisfaction or dissatisfaction do you have with the black bass fishing at Lake Barkley? N=132 Very satisfied 3.0\% Somewhat satisfied 31.1\% Neutral 19.7\% Somewhat dissatisfied 32.6\% Very dissatisfied 13.6\%

8a. If you responded with somewhat or very dissatisfied in question (8) - what is the single most important reason for your dissatisfaction? N=61
Number of fish 82.0\% Size of fish 6.6\% Not happy with regulations 0.0\% Asian carp 9.8\%
water level fluctuations 1.6\%

## Crappie Anglers

9. In general, what level of satisfaction or dissatisfaction do you have with crappie fishing at Lake Barkley? N=112 Very satisfied 4.5\% Somewhat satisfied 40.2\% Neutral 17.9\% Somewhat dissatisfied 23.2\% Very dissatisfied 14.3\%

9a. If you responded with somewhat or very dissatisfied in question (9) - what is the single most important reason for your dissatisfaction? $\mathrm{N}=42$

Number of fish 92.9\% Size of fish 0.0\% Not happy with regulations 0.0\% Asian carp 4.8\% water fluctuations at spawn 2.4\%

## Catfish Anglers

10. In general, what level of satisfaction or dissatisfaction do you have with the catfish fishing at Lake Barkley? N=96 Very satisfied 39.6\%

Somewhat satisfied 44.8\% Neutral 10.4\% Somewhat dissatisfied 1.0\%
Very dissatisfied 4.2\%
10a. If you responded with somewhat or very dissatisfied in question (10) - what is the single most important reason for your dissatisfaction? $\mathrm{N}=5$ Number of fish 60.0\% Size of fish 0.0\% Not happy with regulations 0.0\% Too much commercial fishing 20.0\% Invasive species 20.0\%

## White Bass Anglers

11. In general, what level of satisfaction or dissatisfaction do you have with the white bass fishing at Lake Barkley? $\mathrm{N}=14$ Very satisfied $14.3 \% \quad$ Somewhat satisfied 21.4\% Neutral 21.4\% Somewhat dissatisfied 28.6\%
Very dissatisfied 14.3\%
11a. If you responded with somewhat or very dissatisfied in question (11) - what is the single most important reason for your dissatisfaction? $\mathrm{N}=6$
Number of fish $66.7 \%$ Size of fish 0.0\% Not happy with regulations 0.0\% Asian carp- 33.3\%

## All Anglers

12. Are you satisfied with the current size and creel limits on all sport fish at Lake Barkley? $\mathrm{N}=230$ Yes $90.4 \% \quad$ No $9.6 \%$

12a. If you responded "No" to Question 11, which species are you dissatisfied with and what size and creel limits would you prefer? $\mathrm{N}=22 \quad$ Creel Limit (CL), Length Limit (LL), Slot Limit (SL)

Black Bass- 17" LL; 18" LL; 3 fish/day CL; keep one fish under 15"/day; No one keeps bass for next 5 years; Add tournament restrictions for bass

Largemouth bass- 15-20" SL; 12" LL; 14" LL;
Smallmouth bass- 10-18" SL
Crappie- 12-13" SL; 11" LL; 12" LL; 10 fish/day CL; 15 fish/day CL; "lower" crappie CL;
Catfish- Add limit to fish under 16"; No commercial netting for catfish over 27"
White bass- 10 fish/day CL
13. Are you aware that the Kentucky Department of Fish and Wildlife creates and maintains shallow water stakebeds marked with white poles, and deepwater brushpiles marked with white buoys as fish attractors in Lake Barkley? N=231 Yes 89.2\% No 10.8\%

13a. When you fish Lake Barkley, how regularly do you fish around Department placed fish attractors? N=206 Always 1.9\% Frequently 12.6\% Occasionally 28.2\% Rarely 47.6\% Never 9.7\%

13b. If you answered "Rarely" or "Never", what is the single most important reason you don't fish around Department placed fish attractors? $\mathrm{N}=117$
Over fished 14.5\% No boat 1.7\% No success 36.8\% Don't know their location 16.2\% Wrong water depth $5.1 \%$ Fishes own stuff 6.0\% Boat too big 0.9\% Get snagged 4.3\% Other- "no reason" $5.1 \%$ "; "wrong species" $3.4 \%$; "only fishes them seasonally" 2.6\%; "only fishes dropoffs" 0.9\%; "don't want to disrupt spawning fish" 0.9\%; "only fishes from docks" 0.9\%; fish attractors are only for tourists" 0.9\%
14. If you fish for crappie, do you spider rig (three or more poles per angler at the same time) as your primary method of crappie fishing? $\mathrm{N}=112$
Yes 24.1\% No 75.9\%

15. Do you support or oppose a pole limit while fishing for crappie? $N=111$

Support 43.2\% Oppose 25.2\% No Opinion 31.5\%
15a. If you support a pole limit, what should be the pole limit per person? $\mathrm{N}=48$
$12.1 \% \quad 227.1 \% \quad 327.1 \% \quad 420.8 \% \quad 52.1 \% \quad 610.4 \%>610.4 \%$
16. If you fish for crappie, do you use some form of real time sonar like livescope or a similar system? $\mathrm{N}=112$

Yes 25.9\% No 74.1\%
16a. If "Yes", how often do you use it while crappie fishing? N=29
Always 75.9\% Frequently 10.3\% Occasionally 13.8\% Rarely 0.0\% Never 0.0\%
17. If you fish for catfish in Lake Barkley, which is more important to you: catching trophy fish, or catching more keeper size fish to eat? $\mathrm{N}=96$ Trophy fish $8.3 \%$ Catching keeper fish to eat $71.9 \%$ Both equally important $17.7 \%$ No opinion $2.1 \%$
18. Would you support or oppose a statewide 12-inch minimum size limit on catfish? $N=96$ Support 75.0\% Oppose 18.8\% No Opinion 6.3\%
19. Have you participated in an organized fishing tournament on any body of water within the last twelve months? $\mathrm{N}=229$ Yes 26.2\% No 73.8\%

19a. Were any of the tournaments an alternative format (catch, photo, release; onboard weighing, etc.)? $\mathrm{N}=60$ Yes 8.3\% No 91.7\%

19b. KDFWR is interested in learning more about the number of fishing tournaments in Kentucky. Would you support or oppose a regulation requiring fishing tournaments to register for a free permit that required upcoming tournaments and their ramp locations to be available on the KDFWR website and also required tournaments to report their fishing effort and catch? $\mathrm{N}=60$
Support 83.3\% Oppose 8.3\% No opinion 8.3\%
20. Are you aware that Asian carps are generally considered to be an excellent fish to eat? $\mathrm{N}=230$ Yes 75.7\% No 24.4\%
21. Are you aware that commercial harvest of Asian carps occurs on Lake Barkley? $\mathrm{N}=230$ Yes 86.5\% No 13.5\%

21a. How often do you see commercial fishermen fishing for Asian carps on Lake Barkley? N=199
Always $12.6 \% \quad$ Frequently $19.1 \% \quad$ Occasionally $31.7 \% \quad$ Rarely $23.6 \% \quad$ Never $13.1 \%$

21b. How are your typical interactions with commercial fishermen fishing for Asian carps? $\mathrm{N}=173$
Positive 65.3\% Negative 1.7\% No opinion 33.0\%

# NORTHWESTERN FISHERY DISTRICT 

Project 1: Lake and Tailwater Fishery Surveys

## FINDINGS

Table 1 presents a summary of conditions encountered while sampling at state-owned or managed lakes and ACOE reservoirs during the 2021 field season.

## Nolin River Lake

## Black bass Sampling

Diurnal boat electrofishing to sample the black bass population at Nolin River Lake was conducted in April 2021 (Tables 2-4). Catch rates are consistent with previous samples. Largemouth bass accounted for around $83 \%$ of black bass collected. Total CPUE for largemouth bass in 2021 is slightly lower than the previous survey in 2017, but still on the high end of collections through time. Catch rates for fish $\geq 15.0$ and $\geq 20.0$ in are higher than most previous collections. Largemouth bass PSD and $\mathrm{RSD}_{15}$ have both increased since the 2017 sample and are acceptable.

Diurnal boat electrofishing to survey the black bass population at Nolin River Lake was conducted in October 2021 (Tables 5 and 6). CPUE and relative weights are consistent with previous collections. However, average relative weights could be better.

Slight variability exists concerning catch of larger fish and seems to be attributable to environmental variables at time of sampling rather than changes in the population. The largemouth bass population at Nolin River Lake is relatively stable and performing consistently well (2021 Statewide Assessment Rating = Excellent; Table 7).

## Crappie Sampling

The crappie population was not directly assessed in 2021. It is scheduled to be surveyed during fall 2022.

## White Bass/Walleye Sampling

The white bass and walleye populations were not directly assessed in 2021. They are not scheduled to be surveyed with gill nets until fall 2023.

## Rough River Lake

## Black bass Sampling

Diurnal boat electrofishing to survey the black bass population at Rough River Lake was conducted in April 2021 (Tables 8-10). Largemouth bass account for around $94 \%$ of black bass collected during standardized sampling events. Largemouth bass catch rates are within the range of previous collections. There has been a steady decline in catch rate for fish $\geq 15.0$ and $\geq 20.0$ in since highs in 2012 . However, the 2021 catch rate for 12.0 - to 14.9 -in fish was the highest recorded, which will hopefully translate to an increase in $\geq 15.0$-in fish in 2022 and $\geq 20.0$-in fish down the road. Largemouth bass PSD has increased since the last collection in 2019. A large portion of the increase is attributed to the increase in 12.0- to 14.9 -in fish. If growth continues in the historic range, we should see an increase in $\mathrm{RSD}_{15}$ for 2022 and beyond.

Diurnal boat electrofishing to survey the black bass population at Rough River Lake was conducted again in October 2021 (Tables 11 and 12). Catch rate and condition are consistent with previous samples. Fall catch rates for the different size classes was similar to the 2021 spring survey. Average relative weight for bass $\geq 15.0$ in was good (95), but we would like to see increases for fish 8.0-11.9 and 12.0-14.9 in.

The largemouth bass population at Rough River Lake is experiencing some variability and will be monitored consistently moving forward (2021 Statewide Assessment Rating = Good; Table 13).

## Crappie Sampling

Trap netting to sample Rough River Lake's crappie population was conducted during November (Tables 14-19). A total of 928 crappie ( 810 white crappie) were collected during 84 net-nights ( nn ) for a total CPUE of 11.0 fish/nn. Catch rates were within the range of previous collections. Catch rate for young of year fish was the lowest recorded for the last fourteen samples. However, through time, this parameter is not always an accurate assessor of age class strength. Weather and water conditions can vary tremendously from one year to the next and could easily account for data inconsistencies. Additionally, research has shown that age- 0 crappie are not always accurately represented in standardized samples.

Weights were taken and otoliths removed from a representative sample of each inch class of crappie. Average relative weights were very good for all length groups (96-100 white crappie, 97-103 black crappie). Fish ages 1-3 accounted for approximately $90 \%$ of fish captured, while $55.8 \%$ of fish captured were $7.0-8.0$ in. Growth was improved from the previous four samples but remains well below the exceptional growth recorded from 2002-2009.

There are quite a few chunky 7.0- to 9.0-in fish that will be good, harvestable fish in 2022 and beyond (2021 Statewide Assessment Rating $=$ Good).

## Hybrid Striped Bass Sampling

After five consecutive years of sampling (2016-2020), hybrid striped bass were not surveyed with gill nets in 2021. Data from the telemetry project is in process of being analyzed and will be reported when complete.

## Lake Malone

## Largemouth Bass Sampling

Diurnal boat electrofishing to survey the black bass population at Lake Malone was conducted in April (Tables 2022) and October 2021 (Tables 23-25). Spring catch rate for most length groups was down compared to the 2018 survey. Total CPUE was among the lowest collected during the last fifteen surveys. Sampling conditions were good but sample timing near the end of April may have influenced catch.

Total fall catch rate was nearly identical to the spring; however, fewer fish greater than 15.0 in were collected during this survey. Relative weights for each length group were similar to previous collections but remain below the desired range. Otoliths were collected from a subsample of fish for enumeration of age and growth statistics. Exploitation continues to be low, with fish collected from age- 0 to age- 12 . Growth rates are highly variable across all ages, especially from age- 5 and older. However, mean length at age is reasonable through age- 5 based on fall lengths at capture.

Largemouth bass PSD and $\mathrm{RSD}_{15}$ are within acceptable ranges. Mean WR for all length groups is lower than desired. This may indicate a need to remove bass from within or below the protected slot. An alternative would be to remove the protective slot and manage the lake with the statewide minimum size limit ( 12.0 in ). Data collected in 2022 will be instrumental in determining the next best step. Overall, the bass population at Lake Malone has been relatively stable and performing well for the last two decades (2021 Statewide Assessment Rating = Good; Table 26).

## Channel Catfish Sampling

Tandem hoop netting to assess the channel catfish population was conducted twice in 2021 (9/27-9/30 and 10/2$10 / 4)$. Nets were baited with Zote soap for both samples. The first week of sampling had stable weather, bluebird skies, and air temperature in the low 80s. Only eight individuals were captured during this sampling event. A front was coming through in the next few days, so bait was refreshed, and nets reset for another three net nights.

However, the front weakened, and fewer individuals (5) were captured during the second sampling event. The catfish population will be sampled again in 2022 to document length frequencies and collect individuals for age and growth analyses. Sampling will be attempted in the May/June time frame.

## Mauzy Lake

## Largemouth Bass Sampling

Diurnal boat electrofishing to evaluate the largemouth bass population was conducted in April and October 2021 (Tables 21, 24, 27-29). Both spring and fall sampling conditions were fair, with excessive aquatic vegetation present. Total spring catch rate was one of the lowest recorded since 2009. Almost half of the fish captured were $9.0-10.0$ in. Catch rate for fish $\geq 15.0$ in was the lowest recorded and no fish $\geq 20.0$ in were captured for the first time since 2008. PSD was very low (15) for a consecutive year. Fall catch rate was also low; however, relative weights were consistent with previous collections. Assessment values continue to drop across the board, and the bass population is struggling (2021 Statewide Assessment Rating = Poor; Table 30).

Excessive aquatic vegetation (coontail, Eurasian watermilfoil) continues to be an issue despite management efforts. Additional grass carp (200) were stocked in 2021 and did have a noticeable positive effect. However, a significant amount of vegetation remained throughout the fall. Aquatic vegetation negatively impacted sampling efforts and makes accurate evaluation of the fishery difficult. We are hopeful the grass carp will keep up better with vegetation growth in 2022 and allow for more accurate evaluation of the population. Spring and fall electrofishing surveys are planned for 2022, along with age and growth data collection.

## Bluegill/Redear Sunfish Sampling

Electrofishing to assess the bluegill and redear sunfish populations was not conducted in 2021 due to excessive aquatic vegetation. A survey will be completed during spring 2022 and fish will be collected for age and growth analyses during the fall.

## Lake Renovation Plans

Across all species, growth continues to decline or remain constant at undesirable levels. Additionally, there are numerous undesirable species present in the lake (gizzard shad, crappie spp., flathead catfish, spotted gar, etc.). Ultimately, Mauzy Lake will benefit from another, more complete, renovation. Plans to dredge and deepen extensive shallow areas, upgrade existing bank fishing access, install fish habitat, lime the lake basin, renovate the fishery, and construct a headwater wetland are being created. Mauzy Lake is wholly contained within a WMA and renovation efforts can easily be accomplished.

## Carpenter Lake

## Largemouth Bass

Diurnal boat electrofishing to survey the largemouth bass population at Carpenter Lake was completed in April and October 2021 (Tables 21, 24, 31-33). Total catch rate was the lowest recorded in the last 20 years. The greatest decline was in fish 12.0-14.9 in but there was also a decrease in catch of fish $\geq 15.0$ in. Both PSD and $\mathrm{RSD}_{15}$ are currently at acceptable levels, although an increase in PSD is desirable. Catch rate was higher for the fall sample ( $174.0 \mathrm{fish} / \mathrm{hr}$ compared to $129.0 \mathrm{fish} / \mathrm{hr}$ ) with several more fish $\geq 15.0$ in captured. Body condition was within the range established in previous samples; however, it is desired to see in increase for fish less than 15.0 in. The 2021 Statewide Assessment Rating was Good (Table 34).

## Bluegill/Redear Sunfish Sampling

Electrofishing to assess the bluegill and redear sunfish populations was conducted in May (Tables 35-37). Total catch rate for bluegill dropped back near the long-term average in 2021 after an all-time high collected in 2020.

Again, no bluegill greater than 8.0 in were collected. This is likely the result of abundant gizzard shad and submerged aquatic vegetation. Grass carp (300) were stocked in 2021 to help manage excessive aquatic vegetation (coontail). Several grass carp were documented during the fall bass survey. Bluegill PSD is within the desired range for balanced predator/prey population management; however, a slight increase is desired (2021 Statewide Assessment Rating = Fair - Good; Table 38).

Forty-nine redear sunfish were collected in May in conjunction with bluegill sampling. Total catch rate is near the long-term average but is a decrease from highs in 2019 and 2020. Redear sunfish $>10.0$ in were not documented in 2021 but anglers continue to report catching some quality fish. Due to low population size through time a statewide assessment rating has not been produced for redear sunfish at Carpenter Lake.

Gizzard shad are likely negatively affecting the bluegill and redear sunfish populations. After two failed shad eradication efforts, saugeye were stocked at 85 fish/acre in May 2019. Stocking rate was increased to 100 fish/acre in 2020 and 2021. The stocking rate was increased again during the 2022 Fish Production meeting to 150 fish/acre for 2022. Anglers report catching a few saugeye throughout the year from approximately 10.0 to 18.0 in. Very few have been seen during standard sampling events. Nighttime electrofishing was attempted in November 2020 but no saugeye were captured. No saugeye were collected during 2021 spring bass or bluegill sampling events; however, four saugeye were captured during 2021 fall diurnal largemouth bass sampling ( $10.5,19.2,19.5,19.7 \mathrm{in}$ ). Additional sampling effort will be directed toward saugeye moving forward. It is believed that low population size due to fingerling predation is responsible for the lack of fish documented during standardized sampling events.

## Temperature/Dissolved Oxygen

Temperature and dissolved oxygen profiles were collected at Carpenter Lake on 27 August 2021 (Table 39). Dissolved oxygen dropped below 3.0 ppm at around five feet on the front side and around six feet on the back side of the lake. The lake is very eutrophic, likely resulting from several different sources. The primary of which appears to be a cattle operation on the north side of the lake where cattle have direct access to the lake. The removal of direct access to the lake will be a priority moving forward. Improvements to the aeration system and watershed management are also being investigated as potential avenues to improve water quality.

## Emergency Spillway

The emergency spillway at Carpenter Lake suffered a complete failure during the winter of 2021. Water has undercut the concrete weir and created a channel under the structure. The concrete apron affixed to the front of the weir broke off when all supporting material eroded away. The spillway is now head cutting back toward the lake. Engineering is aware of the issue and plans to repair or replace the structure during summer 2022.

## New Kingfisher Lake

## Largemouth Bass

Electrofishing to assess the largemouth bass population at New Kingfisher Lake was conducted in April and October (Tables 21, 24, 40-42). Spring catch rate decreased from 2021 due to a decrease in fish $<8.0$ and 12.0-14.9 in. Catch rates for fish greater than 15.0 in and greater than 20.0 in remain high. This largemouth bass fishery should continue to grow over the next few years as multiple year classes develop and stabilize. Fall sampling produced fish in good condition and a consistent length distribution (2021 Statewide Assessment Rating = Good; Table 43).

## Bluegill/Redear Sunfish Sampling

The sunfish population was sampled via electrofishing in May (Tables 36, 44-45). Total bluegill CPUE was extremely low compared to samples pre and post renovation. Visibility was much higher than typically encountered during spring sampling and could have accounted for unusually low catch. High catch rates for fish 3.0-5.9 and 6.07.9 in were documented in 2021 and we expected that to translate to high catch rates for larger fish in 2022. This was not documented and hopefully can be attributed to a sampling anomaly as opposed to a real population problem.

Fish were not collected for age and growth analysis in 2021 (2021 Statewide Assessment Rating = Poor - Fair; Table 46).

Gizzard shad were documented in both spring and fall samples. The bluegill population will continue to be monitored in 2022. Winter rotenone treatment will likely be employed during winter 2022/2023.

## Temperature/Dissolved Oxygen

Temperature and dissolved oxygen profiles were collected at New Kingfisher Lake on 27 August 2021 (Table 39). Dissolved oxygen dropped below 3.0 ppm between three and four feet. The lake remains very eutrophic, likely resulting from several different sources. The primary of which is likely the breakdown of terrestrial vegetation that grew in the lake basin during the drawdown for renovation. Water samples will be analyzed in 2022 and remedial efforts will be further explored. Some potential actions include an alum treatment, installation of a bottom diffused aeration system, and/or other phosphorus "locking" products.

## Old Kingfisher Lake

## Largemouth Bass

Electrofishing to assess the largemouth bass population was conducted at Old Kingfisher Lake in April and October (Tables 21, 24, 47-49). A total of 45 bass were collected during the spring survey for a total CPUE of $135.1 \mathrm{fish} / \mathrm{hr}$. High catch rate for fish $<8.0$ inches in 2020 did translate to an increased catch of 8.0- to 11.9-in fish in 2021. Fall sampling did reveal a decline in largemouth bass abundance, presumably related to the oxygen issue in late summer that resulted in both dead and translocated fish. Relative weights continue to be good for fish $\geq 15.0$ in but could improve for the smaller length groups. Additional fish habitat targeted toward small sunfish may prove beneficial. Fish were not collected for age and growth analysis in 2021 (2021 Statewide Assessment Rating = Poor Fair; Table 50).

## Bluegill/Redear Sunfish Sampling

The sunfish population at Old Kingfisher Lake was sampled via electrofishing in May (Tables 36, 51-52). Total bluegill CPUE was 746.7 fish $/ \mathrm{hr}$, which is a decrease from 2020 . Total numbers remain above the desired range but are still shifting around as the bass population changes as well. As the largemouth bass population grows and stabilizes, sunfish growth and size structure will improve. Age-growth data will be collected after populations have stabilized. Fish were not collected for age and growth analysis in 2021 (Statewide Assessment Rating = Fair Good; Table 53). Only twelve redear sunfish were collected during standardized sampling, those ranging from 1.09.0 in .

Gizzard shad were documented at both Old and New Kingfisher lakes in 2018. Given the high productivity of the Kingfisher lakes, it is likely the shad populations will expand quickly. They will be monitored along with the sunfish to determine if shad control strategies need to be employed. It is likely that a winter shad rotenone treatment will be completed during winter 2022/2023.

## Temperature/Dissolved Oxygen

Temperature and dissolved oxygen profiles were collected at Old Kingfisher Lake on 27 August 2021 (Table 39). Dissolved oxygen dropped below 3.0 ppm between two and three feet. Obviously, the lake remains very eutrophic, likely resulting from several different sources. The primary of which is likely the breakdown of terrestrial vegetation that grew in the lake basin during the drawdown for renovation. Anoxic conditions at the water-sediment interface during stratification releases a large amount of phosphorus into the water column, leading to heavy planktonic algae blooms. Water samples will be analyzed in 2022 and remedial efforts will be further explored. Some potential actions include an alum treatment, installation of a bottom diffused aeration system, and/or other phosphorus "locking" products.

There was an oxygen related fish kill in 2021. After several cloudy and cool days during late summer a believed planktonic/blue-green algae die off resulted in stressed and dying fish. Several larger, stressed largemouth bass beached themselves on the boat ramp and were picked up by hand and transported across the road to New Kingfisher Lake. There did not appear to be a significant oxygen issue occurring in New Kingfisher Lake at the same time and those fish appeared to swim away unharmed. Many shad, crappie and bluegill died during this event, along with several largemouth bass and channel catfish.

## Washburn Lake

## Largemouth Bass

Electrofishing to assess the largemouth bass population was conducted at Washburn Lake in April and October (Tables 21, 24, 54-56). Total CPUE for the spring ( 372.0 fish $/ \mathrm{hr}$ ) is slightly above the long-term average. Fish 12.020.0 in were noticeably missing once again. Good numbers of 8.0- to 14.9 -in fish seen in 2018 did not show up in the larger length groups in spring or fall samples in 2021. PSD is extremely low (7), due to an abundance of fish 8.012.0 in. Recruitment is high and average relative weight for the 8.0 - to 11.9 -in fish is 80 , indicating crowding of small fish. Spring catch of two fish $>20.0$ in inflated the CPUE for the $\geq 20.0$-in length group, making it score full points in that category. Additionally, a full score for CPUE age-1 fish due to high numbers of small fish may not actually be a good thing. Fall sampling did not produce a fish over 15.0 in (2021 Statewide Assessment Rating = Fair - Good; Table 57). Data collected in 2022 will determine the next steps for the lake. Although we are focused on a trophy sunfish fishery with abundant small bass, it appears likely that some small bass will need to be removed to allow for some improvement in growth. A slight increase in larger bass will be necessary to keep the sunfish from becoming crowded in the 5.0 - to 7.0 -in range. A subsample of bass will be collected for age and growth analyses during fall 2022 sampling.

## Bluegill/Redear Sunfish Sampling

The sunfish population at Washburn Lake was sampled via electrofishing in May (Tables 36, 58-59). Total CPUE for bluegill decreased in 2021. Catch rate for fish $<3.0$ in remained constant, catch for fish 3.0-5.9 and 6.0-7.9 in decreased, and catch rate for fish $\geq 8.0$ in increased from 2020. Bluegill PSD is 37 and should continue to increase if crowding does not occur. Age and growth data was not collected in 2021 (2021 Statewide Assessment Rating = Fair - Good; Table 60).

Total CPUE for redear sunfish increased some from 2020, with most of the increase being attributed to a near threefold increase in fish $\geq 8.0 \mathrm{in}$. Small ( $<6.0$-in) redear were in very low abundance, likely due to the high numbers of small bass. Redear sunfish PSD is 92 , which is very good if recruitment can be maintained. However, we have not collected a redear sunfish $\geq 10.0$ in to date. Age and growth data was not collected in 2021 (2021 Statewide Assessment Rating = Fair - Good; Table 61).

## Lake Renovation

Washburn Lake would benefit greatly from another full renovation. Plans to dredge and deepen extensive shallow areas, create more bank fishing access, install fish habitat, lime the lake, renovate the fishery, create a headwater wetland, and replace the existing water control structure have been created. The current water control tower leaks profusely and could fail at any time, requiring plans to be in place to move forward with a renovation when necessary. The lakeshore that adjoins the county road needs to be stabilized and parking added for angler safety. This renovation will require more planning, cooperation, and financial commitment than the renovation at Mauzy Lake due to the proximity of private landowners and county roads serving as two of the lake boundaries.

# SOUTHWESTERN FISHERY DISTRICT 

Project 1: Lake and Tailwater Fishery Surveys

## FINDINGS

Lake sampling conditions are summarized in Table 1.

## Barren River Lake (10,000 acres)

## Black Bass

Black bass were collected with diurnal electrofishing in late-April to early-May from both lake arms (Tables 2-5) and once again in the fall (Tables 6-11). A total of 599 black bass were collected in the spring at a rate of 99.8 fish $/ \mathrm{hr}$ (Table 2). Largemouth bass made up $90 \%$ of the total catch while spotted bass made up $10 \%$, and their distribution remains tied to the lower $1 / 3$ of the reservoir. The overall catch rate for largemouth bass $(90.0 \mathrm{fish} / \mathrm{hr})$ was the lowest noted in the last 10 years (Table 3), and is due to lower-than-average catch rates of fish $<12.0 \mathrm{in}$. Catch rate of the 8.0 - to 11.9 -in length group ( 20.0 fish $/ \mathrm{hr}$ ) suggests a poor 2019 year class and the dampened catch rate of the 12.0- to 14.9 -in length group suggests consecutive years of spring flooding negatively affected largemouth bass recruitment. Overwinter survival of the 2020 largemouth year-class was the poorest in the last 10 years (age-1 CPUE $=3.3$ fish $/ \mathrm{hr}$.; Table 7) despite average numbers of $\geq 5.0$-in yoy bass ( $\mathrm{CPUE}=32.7 \mathrm{fish} / \mathrm{hr}$; Table 7) entering the winter. The largemouth bass population assessment dropped from "Excellent" to "Good" due to the poor spawn of 2019 (Table 4).

Largemouth bass size structure indices remain on the high end of the range (PSD $=77$ and $\mathrm{RSD}_{15}=36$; Table 5) and were similar to previous years. Spotted bass size structure remains high quality as well ( $\mathrm{PSD}=93$ and $\mathrm{RSD}_{14}=47$ ), even with the low numbers of fish sampled. The smallmouth bass population remains poorly represented in samples (Tables 2 and 6), but larger fish are reported by anglers.

Fall young of year sampling suggests a very good 2021 year-class. Age-0 CPUE ( $302.0 \mathrm{fish} / \mathrm{hr}$; Table 7) was the second highest within the past 10 years. Age-0 CPUE $\geq 5.0$ in ( 70.0 fish/hr) was the highest it has been for the past 10 years. Age- 0 largemouth bass mean length ( 4.3 in ) was right around average for the past 10 years. Though age- 0 largemouth bass production was highest in the Barren River arm of the lake (Walnut Creek and Peter Creek sites), Beaver Creek fish grew faster and yielded more $\geq 5.0$-in bass than all other sites combined (Table 6). Poorer growth and numbers characterized the lower end of the lake (the Peninsula sites). Largemouth bass made up most of the fall sample ( $95 \%$ ), while spotted bass made up the other $5 \%$ (Table 6). Smallmouth bass were nearly nonexistent in these samples.

Largemouth and spotted bass were aged in the fall (Tables $8-11$ ). The largemouth bass population is carried by the 2018 year class when the young of year are removed from the total (Table 8). Largemouth bass reached 15.0 inches in 4.1 years (calculated from Von Bertalanffy equation; FAST 3.0 software). Spotted bass needed 3.9 years to reach 12.0 in (Von Bertalanffy equation; FAST 3.0 software). The largemouth bass age sample had 11 year classes represented with the oldest representative coming from the 2009 year class ( $12+$ years old).

## Crappie

Trap netting for crappie yielded 1811 total crappie ( 877 black crappie and 934 white crappie) in 74 net-nights (Table 12). The crappie population appears to remain an even mix of both species ( $51 \%$ white and $48 \%$ black). Age- 0 catch rates of both species represented $8 \%$ of the total crappie catch ( $6 \%$ of white crappie and $10 \%$ of black crappie catch rates; Tables 13-16). The population is carried by the 2018 and 2019 year classes with $80 \%$ of the fish sampled from these two year classes. The 2020 and 2021 year classes were present in very low numbers for both white crappie (CPUE age- $1=1.3$ fish $/ \mathrm{nn}$ and CPUE age- $0=0.8$ fish $/ \mathrm{nn}$ ) and black crappie (CPUE age- $1=1.4 \mathrm{fish} / \mathrm{nn}$ and CPUE age- $0=1.2$ fish $/ \mathrm{nn}$; Tables 17 and 18). White crappie reached harvestable size ( 10.0 in ) in 3.5 years (calculated from Von Bertalanffy equation; FAST 3.0 software). Black crappie reached harvestable size ( 10.0 in) in 5.2 years (calculated from Von Bertalanffy equation; FAST 3.0 software). The assessment rating increased to "Good" for black crappie and remained "Good" for white crappie (Tables 17 and 18) and resulted in an increase in the overall crappie
assessment rating to "Good" (Table 19). White crappie size structure indices increased from previous sampling while black crappie indices decreased (White - PSD: 85, RSD: 16 and Black - PSD:15, RSD: 1; Table 20). The lengthweight equations for black crappie $(\mathrm{n}=788)$ and white crappie $(\mathrm{n}=892)$ were similar to prior years:

Black crappie $\log _{10}($ weight $)=-5.4803+3.2645^{*} \log _{10}($ Length $)$
White crappie $\log _{10}($ weight $)=-5.9873+3.4636 * \log _{10}($ Length $)$

## Blue Catfish

Blue catfish were collected with diurnal electrofishing in mid-August and early-September from both lake arms. A total of 80 blue catfish were collected at a rate of 35.6 fish $/ \mathrm{hr}$ (Table 21). Fish $<15.0$ inches in length were taken for aging to assess spawning contributions from non-stocking years (2020 and 2021). Two age-0 naturally spawned fish were noted (Table 22). All other fish came from previous stockings.

Creel Survey: Results of a roving, daytime creel survey are presented in Tables 23-33. Anglers made an estimated 40,565 trips and fished for 199,952 hours with the average trip approximating 4.93 hours. The number of trips is up slightly from the 2016 creel survey ( 38,867 in 2016) and anglers caught 112,208 more fish but harvested 38,637 less fish compared to 2016 (Table 23). Overall, anglers caught 336,364 fish and harvested 58,570 of the fish caught. Black bass continue to be the most sought-after fish species, accounting for $47 \%$ of effort followed by crappie ( $21 \%$ ), anything ( $12 \%$ ), catfish ( $11 \%$ ), morone ( $6 \%$ ), and panfish ( $3 \%$; Table 24 ).

Bass angler trips $(19,101)$, hours fished by bass anglers $(94,150)$, and the catch rate ( $0.73 \mathrm{fish} / \mathrm{hr}$ ) increased from the 2016 creel survey ( 18,097 trips, 75,782 hours, and 0.47 fish $/ \mathrm{hr}$, respectively; Tables 26 and 30 ). The estimated 81,059 largemouth bass caught is an increase from the previous two creel surveys (2016: 31,315 and 2010: 65,300). The estimated largemouth bass harvest $(14,141)$ also increased from the previous two creels $(2016: 8,670$ and 2010: 6,677; Tables 25 and 26).

Crappie angler trips $(8,585)$ decreased by 4,395 from the 2016 creel and the number of hours fished for crappie decreased by 12,037 ( 42,317 hours in 2021 ; Tables 27 and 31 ). High water levels during early spring likely reduced angler hours and trips. The crappie catch rate ( 3.90 fish/hr) was up from the 2016 survey, but the harvest rate ( 0.51 fish $/ \mathrm{hr}$ ) was down by almost half from the 2016 survey ( 1.15 fish $/ \mathrm{hr}$ ). Crappie harvest only represented $12 \%$ of total crappie caught $(201,280)$. The crappie catch was dominated by white crappie at $81 \%(162,229$ fish; Table 25$)$ and sublegal fish.

Morone angler trips $(2,547)$ increased by $77 \%$ and the hours fished for morone $(12,554)$ increased by $65 \%$ from the 2016 creel survey (Tables 28 and 32). The Morone catch rate ( 0.46 fish/hr) and harvest rate ( 0.29 fish $/ \mathrm{hr}$ ) were similar to 2016. The morone catch was dominated by hybrid striped bass ( $69 \%$ ) and over half ( $63 \%$ ) of the fish harvested were $\geq 15.0$ in (Table 25).

Catfish angler trips $(4,575)$ increased from the previous two creel surveys (2016: 2,078 and 2010: 3,169) and the hours fished for catfish $(22,549)$ significantly increased from the two previous surveys $(2016: 8,704$ and 2010:13,303; Tables 29 and 33). The estimated 15,833 catfish caught increased from the two previous surveys (2016: 12,902 and 2010: 11,952); however, the estimated harvest for $2021(9,737)$ decreased slightly from 2016 $(9,760)$ but was still significantly higher than $2010(894)$. More channel catfish were caught $(10,883)$ than either blue catfish $(4,444)$ or flathead catfish (502). However, of those channel catfish caught, only $57 \%$ were harvested, while $73 \%$ of the blue catfish and $71 \%$ of the flathead catfish caught were harvested (Table 25).

Angler Attitude Survey: Angler attitude results are presented in Figure 1. Anglers identified bass (47.4\%) as the species they fished for the most, which is similar to the 2016 creel survey ( $44.3 \%$ ). Crappie ( $32.9 \%$ ) were the next most fished for species, but this number decreased from 2016 ( $41.5 \%$ ). Catfish ( $13.2 \%$ ) were the third most fished for and this number more than doubled from 2016 ( $5.2 \%$ ). Hybrid striped bass ( $2.8 \%$ ) was the least popular fish, coming in behind "Other" ( $3.8 \%$ ), and it also decreased from 2016 ( $5.2 \%$ ). Overall satisfaction (very satisfied to somewhat satisfied) for bass, crappie, hybrid striped bass, and catfish ranged from 54-82\%.

Response of catfish anglers to what methods they used most included hook and line (86\%), floating jugs (29\%), and hand fishing (2\%).

Most of the anglers ( $60 \%$ ) at Barren River Lake prefer brush pile type fish attractors followed by no preference ( $23 \%$ ), hinge-cut/laydown tree ( $12 \%$ ), and plastic ( $5 \%$ ). When asked if they had fished plastic structures, most of the anglers ( $79 \%$ ) did not use the plastic structures that KDFWR has put in the lake. Of those anglers that have fished plastic structures, about half ( $54 \%$ ) like the plastic trees the best followed by the Mossbacks ( $26 \%$ ), and then other ( $20 \%$ ). When asked for the reason why they liked plastic fish attractors, "Doesn't hang up as much" (35\%), "Durability" (24\%), and "Holds a lot of fish" (18\%) were the top three answers. When asked for the reason why they disliked plastic fish attractors, anglers top three reasons were "Other" (37\%), "Doesn't hold many fish" (30\%), and "Harder to locate" $(16 \%)$. Some of the responses for the other category were "not enough", "brush is better", "can't locate".

Most anglers (82\%) fished Barren River Lake with regularity (more than 10 time annually) and not surprisingly, the majority of the anglers were from Kentucky ( $98 \%$ ) and $71 \%$ of those anglers traveled less than 30 miles to fish the lake. Two states were represented by out-of-state anglers ( $n=4$; TN and AL), comprising only $2 \%$ of anglers compared to the $6 \%$ of nonresident anglers identified by the creel survey.

## Briggs Lake (18 acres)

## Sunfish

The sunfish population was sampled by diurnal electrofishing on May 6 (Table 34). Overall CPUE of bluegill (529.3 fish $/ \mathrm{hr}$ ) was the second highest over the past twelve years (Table 35). The catch rates of bluegill in the 3.0 - to 5.9 -in length group ( $325.3 \mathrm{fish} / \mathrm{hr}$ ) and 6.0- to 7.9-in length group ( $176.0 \mathrm{fish} / \mathrm{hr}$ ) were the highest they have been in the past 12 years, but the $\geq 8.0$-in length group saw the lowest catch rate ( 1.3 fish $/ \mathrm{hr}$ ) from the past 12 years. Redear sunfish CPUE ( 162.7 fish $/ \mathrm{hr}$ ) was higher than the average from previous years (Table 34). The catch rate of the $\geq 10.0$-in length group ( $2.7 \mathrm{fish} / \mathrm{hr}$ ) was below the average for the previous years (Table 36), while the catch rate of the 6.0 - to 7.9 -in length group ( $105.3 \mathrm{fish} / \mathrm{hr}$ ) was the highest is has been in the past 12 years. Size structure indices for bluegill $($ PSD $=35)$ dipped from $2019(P S D=39)$ while indices for redear sunfish $(P S D=70)$ continued to reflect a high-quality fishery (Table 37). The population assessment for bluegill dipped to "Good", while the redear sunfish remained "Excellent" (Tables 38 and 39).

## Black Bass

Nocturnal largemouth bass electrofishing samples were collected in April (Tables 40-42). The catch rate (182.4 fish $/ \mathrm{hr}$ ) was the lowest it has ever been over the past 15 years (Table 41). The PSD value (37) was lower than in 2016 but remained higher than 2012 (Table 42). Since the lake is managed for bluegill/redear sunfish, the bass population assessment table was not included.

## Marion County Lake ( 25 acres)

## Sunfish

Diurnal electrofishing results for bluegill and redear sunfish are presented in Tables 43-48. The overall catch rate for bluegill ( 427.0 fish $/ \mathrm{hr}$ ) was above average for the past 14 years, while the catch rate for redear sunfish ( 125.0 fish $/ \mathrm{hr}$ ) was the second highest over the past 14 years (Tables 43-45). The size structure of both populations was very good (bluegill PSD $=62$, redear PSD $=70$ ) when compared to previous years (Table 46). The catch rate of $\geq 6.0$-in bluegill ( 248.0 fish $/ \mathrm{hr}$ ) was the highest it has been in the past 14 years and the catch rate of $\geq 8.0$-in bluegill ( $10.0 \mathrm{fish} / \mathrm{hr)}$ ) was the third highest when compared to the past 14 years. As a result, the bluegill population assessment was "Excellent" (Table 47). The catch rate of $\geq 8.0$-in redear ( $59.0 \mathrm{fish} / \mathrm{hr}$ ) was the second highest over the past 14 years and more than doubled the management objective of $25.0 \mathrm{fish} / \mathrm{hr}$ (Table 48). The catch rate of $\geq 10.0$-in fish ( 4.0 fish $/ \mathrm{hr}$ ) decreased from the previous sample but was still above average. The redear sunfish population assessment achieved an "Excellent" rating (Table 48).

## West Fork Drakes Reservoir

## Black Bass

Results of diurnal bass electrofishing in May (Tables 49-52) were well below average at 68.0 fish/hr due to lower catch rates of all length groups $<15.0$ in (Table 50). Size structure (PSD 46; Table 51) deceptively "improved" due to the lack of sub- 15.0 -in fish. Poor recruitment seems to have plagued this system despite it being a shallow riverrun system with gizzard shad, good productivity (secchi depths in 2 - to 3 -foot range), and immense shallow cover or nursery areas. Erratic spring conditions (high rainfall) seems to be the overriding factor in the poor recruitment. The largemouth bass population assessment remained "Fair" due to slight increases in the number of larger ( $\geq 15.0$-in and $\geq 20.0$-in) fish (Table 52).

## Sunfish

Electrofishing results for bluegill and redear sunfish from mid-May were similar to prior years for all length groups except larger fish (Tables 53-58). Lack of larger fish influenced the size structure assessments for both species (redear $\mathrm{PSD}=35$; bluegill $\mathrm{PSD}=7$ ), causing the redear population assessment rating to drop to "Poor" and bluegill population assessment remaining "Fair" (Tables 56-58). Reduction in bass numbers may be a causative factor in reduction of larger sunfish.

## Green River Lake

## Muskellunge

High water (3-17 ft above summer pool) during late-winter through mid-April did not permit muskie sampling either by electrofishing or fyke nets in 2021. This marks the third year muskie sampling has been knocked out by high water.

## Black Bass

Nocturnal bass electrofishing was conducted on the upper and lower ends of each lake arm (Green River and Robinson Creek) during late April and early May (Tables 1 and 59). The overall largemouth CPUE of 125.8 fish/hr was similar to the last few years $(2019=140.5 ; 2018=137.2$; Table 60$)$ as were most length group catch rates. Catch rate of smaller largemouth bass ( $<8.0 \mathrm{in} ; 16.5 \mathrm{fish} / \mathrm{hr}$ ) was slightly lower than average as expected based on low 2020 fall catch rates of YOY bass (Table 64). Largemouth size structure indices (PSD $=61$; RSD $=29$ ) were similar to previous years' $(\mathrm{PSD}=69 ; \mathrm{RSD}=32$; Table 61$)$. The population assessment for largemouth bass remained "Excellent"; similar to the last ten years (Table 62). The age-1 CPUE (14.67 fish/hr; Table 64) of the 2020 largemouth bass year class was average in relation to prior years.

The spotted bass catch rate ( 45.8 fish $/ \mathrm{hr}$; Table 59) was less than the previous two years $(2019=79.17 ; 2018=66$ fish $/ \mathrm{hr}$ ) but was still in the normal range. The population continues to produce notable numbers of fish $\geq 12.0$ inches in length (PSD $=31$; Table 61) which was rare prior to the appearance of alewife in 2004.

Fall YOY sampling (Tables 63 and 64) suggests a moderately-strong 2021 largemouth bass year class as age- 0 CPUE $\geq 5.0$ in ( 24.5 fish $/ \mathrm{hr}$ ) was slightly higher than the average of the last 10 years. The lower lake sites from both lake arms continue to produce less age- 0 fish. Higher overall catch rate of age-0 largemouth ( $70.2 \mathrm{fish} / \mathrm{hr}$ ) was bolstered by larger age-0 fish from upper lake sites, perhaps giving better odds for the 2021 year-class to be stronger than average.

## Metcalfe County Lake (22 acres)

## Bluegill

Information from diurnal bluegill sampling on April 27 (Table 1) is presented in Tables 65-68. Overall CPUE (667.2 fish/hr; Table 66) and length group CPUE's were similar to recent years. Size structure index (PSD = 48; Table 67) returned to historic values ( $\mathrm{PSD}=37-47$ for 2005-2016) after a slight dip in 2018 ( $\mathrm{PSD}=26$ ). The bluegill population assessment remained "Good" (Table 68), similar to previous years.

## Mill Creek Lake (109 acres)

## Sunfish

Results of diurnal sunfish electrofishing on May 18 are presented in Tables 69-72. The overall bluegill CPUE ( $659.0 \mathrm{fish} / \mathrm{hr}$ ) was similar to previous years (Table 70). The bluegill population size structure remains dominated by intermediate-size fish ( $435.0 \mathrm{fish} / \mathrm{hr}$; PSD $=7$ ), similar to previous years (Tables 70 and 71 ). The population assessment remains "Poor" (Table 63) despite a substantial stocking of largemouth bass ( $\mathrm{n}=542 ; 5$ bass/A; 5.0-11.0 in) in May of 2020. Redear sunfish catch in 2021 was the highest seen at the lake ( 61.0 fish $/ \mathrm{hr}$; Table 69). Previous samples never exceeded 17.0 fish $/ \mathrm{hr}$. This increase may be the result of increased bass predation pressure. However, the presence of a substantial gizzard shad population and lower productivity seem the likely factors hindering overall sunfish population improvements.

## Shanty Hollow Lake (136 acres)

## Black Bass

Nocturnal bass sampling on April 15 yielded an overall largemouth bass CPUE of 207.7 fish/hr (Table 73); slightly less than historical average (Table 74). The size structure index (PSD $=21$, Table 75) was well below previous years due to reduced presence of the 12.0 - to 14 -in bass (Table 74). The largemouth bass population still suffers from persisting poor recruitment to larger length classes (Table 76). The population assessment retained a "Good" rating similar to most years. Removal of smaller-size bass ( $\mathrm{n}=171$ ) plus resumption of fertilization in 2016 did not seem to improve bass size structure or bluegill production. Chronic low water levels ( $6-12 \mathrm{ft}$ reductions) from late summer through fall still plague the lake annually and likely serves to confound bass and sunfish interactions.

## Sunfish

Sunfish (bluegill and redear) were sampled by nocturnal electrofishing on May 27 after two substandard diurnal attempts on May 19 and 23 (Tables 1 and 77). Catch rate of intermediate-size bluegill dipped substantially from 2019 and was below historic ranges (Table 78). Bluegill size structure ( $\mathrm{PSD}=48$; Table 80 ) improved markedly from 2017 and 2019 (PSD = 27 and 31, respectively) reflecting an increase in larger sizes ( $6.0-$ to 7.9 -in fish). Large fish abundance ( 8.0 -in plus) remained low, similar to prior years. The bluegill population assessment remains "Good", similar to the last 10 years (Table 81).

The redear sunfish population remains low density ( $\mathrm{CPUE}=28.7$ fish/hr; Tables 77 and 79 ) with good size structure ( $\mathrm{PSD}=50$, Table 80 ) outside of a consistent absence of large fish ( $10.0-\mathrm{in}$ plus). The population assessment rated "Good", similar to previous years (Table 82).

## Spurlington Lake (25 acres)

## Sunfish

The sunfish population was sampled by diurnal electrofishing on May 20 (Tables 1 and 83). Overall catch rate ( 1190.0 fish $/ \mathrm{hr}$.) and most size group catch rates were similar to previous years (Table 84). Catch rate of the 6.0- to 7.9 -in length group ( $186.0 \mathrm{fish} / \mathrm{hr}$ ) was significantly higher than recent years (Table 84). Bluegill size structure is still dominated by intermediate-size fish ( $\mathrm{PSD}=22$; Table 86), but the population assessment remained "Excellent" (Table 87).

The redear sunfish population overall catch rate was at an all-time high (164.0 fish/hr; Tables 83 and 85); however, the population assessment is not available due to the lack of age data.

## Channel Catfish

Tandem hoop nets were deployed from August 20-26 with fair results for channel catfish ( $\mathrm{n}=36$; Table 88). Channel catfish representing five year classes (age-1+ to 6+; Table 89) suggests some reproduction occurs, but stocked year classes carry the fishery. Recent stocking rate changes may explain some of decline in catch as the lake was only stocked once in the last 3 years (2016; at 25 fish/ac). Channel catfish of all length groups were represented and condition of all length groups was good (Table 90).

Table 1. Lake sampling conditions in the Southwestern Fisheries District in 2021.

| Lake | Date | Species | Water temp. <br> surface (F) | Conductivity (umhos) | Secchi <br> (in.) | Comments |

CENTRAL FISHERIES DISTRICT<br>Project 1: Lake and Tailwater Fishery Surveys<br>FINDINGS

Lake sampling conditions for 2021 are summarized in Table 1.

## Taylorsville Lake (3,050 acres)

Spring nocturnal electrofishing was completed in April 2021 to assess the black bass population. Three sections (Big Beech Creek, Ashes/Jacks Creek, and Van Buren area) of Taylorsville Lake were sampled for 7.5 hours ( 2.5 hours per section; 15-minute runs). Length distribution and CPUE for largemouth bass are presented in Tables 2 and 3. The catch rate of bass collected in 2021 ( $149.3 \mathrm{fish} / \mathrm{hr}$ ) was higher than the lake's historic average of 120.4 fish $/ \mathrm{hr}$. Catch rate for keeper-size bass ( $\geq 15.0 \mathrm{in}$ ) was $20.9 \mathrm{fish} / \mathrm{hr}$; higher than the lake average ( $19.0 \mathrm{fish} / \mathrm{hr}$ ). The Ashes Creek area recorded the highest catch rate for largemouth bass. The PSD for largemouth bass was 72, which was higher than the lake's average of 57 (Table 4). Additionally, the $\mathrm{RSD}_{15}$ value was 15 , which is less than the lake's average of 22. The largemouth bass population assessment score, based on spring electrofishing data, was "Excellent", which is above the average rating of "Good" at Taylorsville Lake (Table 5). Length frequency, relative weights, and index for year class strength at age-0 for largemouth bass, based on October 2021 electrofishing data, are presented in Tables 6-8. Average body condition for largemouth bass in $2021\left(\mathrm{~W}_{\mathrm{r}}=92\right.$; Table 7) was acceptable, but lower than the lake's historic average $\left(\mathrm{W}_{\mathrm{r}}=96\right)$. Catch rate of age-0 largemouth bass in the fall of 2021 ( 18.9 fish $/ \mathrm{hr}$ ) was lower than the lake's historic average of 38.4 fish $/ \mathrm{hr}$ (Table 8). The year class strength model indicated below average recruitment for young-of-the-year largemouth bass in 2021, this was the fourth straight year of below average recruitment. A total of 25,002 (8.2 fish/acre) surplus largemouth bass (3.8-4.2 in) were stocked into Taylorsville Lake in August 2021. An additional 633 ( 0.2 fish/acre) largemouth bass ( $4.0-11.0$ in), removed from Beaver Lake, were stocked into Taylorsville Lake in June 2021.

Trap netting effort for crappie (Table 9) resulted in the collection of 720 white crappie and 100 black crappie. Crappie were sampled with trap nets for 48 net-nights. PSD and $\mathrm{RSD}_{10}$ values are shown in Table 10. Age and growth determinations and age frequency for black and white crappie were completed using otoliths (Tables 11-14). Age studies indicated both white and black crappie start reaching the 10.0 -in size limit between age- 2 and age- 3 . The crappie population assessment scores (Tables 15 and 16) rated white crappie as "Good" and black crappie as "Fair". Historically, the crappie population at Taylorsville Lake has been very cyclic with peaks occurring every 7 to 9 years. More recently, there have been significant spawns in 2013, 2015 and 2019 based off trap net data. Body condition of white and black crappie in the fall of 2021 was acceptable (Table 17).

Fall gill netting for hybrid striped bass, white bass, and saugeye was conducted in October 2021 (Tables 18-29). Hybrid striped bass were captured in 8 net-nights for a CPUE of 5.0 fish $/ \mathrm{nn}$. Age and growth studies were completed for hybrid striped bass using otoliths (Tables 19 and 20). Hybrid striped bass continue to show good growth, reaching 15.0 in between age-1 and age-2. The relative weight $\left(W_{r}\right)$ index for hybrid striped bass was 86 in 2021 which is equal to the historic average $\left(\mathrm{W}_{\mathrm{r}}=86\right)$ at Taylorsville Lake (Table 21). The population assessment for hybrid striped bass was rated at "Fair" (Table 22). Taylorsville Lake was stocked with 61,254 (20.1 fish/acre; 1.3 in ) reciprocal crossed hybrid striped bass in June 2021. No original cross hybrid striped bass were stocked in 2021. Data for white bass collected during fall 2021 gill netting studies are presented in Tables 18 and 23-26. Age and growth studies indicate white bass average over 11.0 in by age- 2 and good year classes were produced in 2018, 2019, and 2020 (Tables 23 and 24). Relative weight values ( $\mathrm{W}_{\mathrm{r}}=90$ ) revealed less than average body conditions for all sizes of white bass in 2021 (Table 25). The white bass population assessment was rated "Fair"; an average rating for white bass at Taylorsville Lake (Table 26).

Saugeye were collected during fall gill netting in October 2021. A total of 84 saugeye were collected ranging from 10 to 25 in (Table 18). Age and growth studies were completed using otoliths. Calculations indicated on average, saugeye reach the 14.0 -in size limit between age- 1 and age-2, and 20.0 in between age- 3 and age- 4 (Table 27). All
seven stocked year classes were represented in the age and growth sample (Table 28). The relative weight $\left(\mathrm{W}_{\mathrm{r}}\right)$ index for saugeye (95) showed good body condition (Table 29). Taylorsville Lake was stocked with 360,026 saugeye fry ( 118.0 fish/acre) in April and an additional 74,145 saugeye ( 24.3 fish/acre; 1.23 in) in May 2021.

Summer diurnal low-pulse electrofishing was completed in July 2021 to assess the blue catfish population. Two sections (Lower Lake: Big Beech Creek and Ashes/Jacks Creek, and Upper Lake: Chowning Lane area) of Taylorsville Lake were sampled for 3.0 hours ( 15 -minute runs). Two hundred and ninety-four blue catfish were collected in the lower section compared to 157 blue catfish collected in the upper section of the lake (Table 30). The number of blue catfish collected in 2021 ( $150.3 \mathrm{fish} / \mathrm{hr}$ ) was higher than the lake's historic average of $127.9 \mathrm{fish} / \mathrm{hr}$ (Table 31). Relative weight values revealed good body condition for all sizes of blue catfish (Table 32). A total of 24,000 (7.9 fish/acre) blue catfish ( 6.5 in ) were stocked in Taylorsville Lake during March 2021.

## Herrington Lake (2,410 acres)

Diurnal electrofishing studies were completed in March and April 2021 to monitor the crappie population. Upper, middle, and lower lake sections were sampled for a total of 4.5 hours. A total of 44 crappie were collected in 2021 (Table 33). The PSD's for both white (100) and black (97) crappie were similar to the lake's historical averages of 97 for both species (Table 34). The overall catch was dominated by black crappie, which made up $84.1 \%$ of the crappie sampled at Herrington Lake in 2021. Age and growth studies were only completed on the black crappie population due to low numbers of white crappie in the sample. Age and growth studies showed black crappie reached 10.0 in between age-2 and age-3 (Table 35). The black crappie population was dominated by the age-2-year class (2019 year class) in 2021 (Table 36). A population assessment was developed for spring electrofishing for white and black crappie at Herrington Lake. The population assessment for white crappie indicated a "Poor" population in 2021, below the lake's average of "Fair" (Table 37). The population assessment for black crappie was "Poor" for 2021 (Table 38), also below the lake's average of "Fair". Herrington Lake was stocked with 19,758 black crappie ( 1.4 in ) in May and an additional 40,134 black crappie ( 2.3 in ) in August 2021. Therefore, a total of 59,892 (24.9 fish/acre; $1.4-2.3$ in) black crappie were stocked in 2021.

Spring diurnal electrofishing studies were completed in April 2021 to monitor the black bass population. Upper, middle, and lower sections were sampled for a total of 7.5 hours ( 2.5 hours per section). Species composition, relative abundance, and CPUE of black bass collected in the spring are presented in Table 39. Largemouth bass ( $85.3 \%$ ) dominate the black bass fishery at Herrington Lake. Catch rate of largemouth bass in 2021 ( 76.8 fish $/ \mathrm{hr}$ ) was lower than the lake's historic average of 116.0 fish/hr (Table 40). Fluctuations in the overall catch rates at Herrington Lake seems to be related to lake level during sampling. The higher the lake level the lower the catch rate of bass. Catch rate for keeper bass ( $\geq 12.0 \mathrm{in}$ ) was $44.7 \mathrm{fish} / \mathrm{hr}$, lower than the lake's historic average ( $49.6 \mathrm{fish} / \mathrm{hr}$ ). The PSD for largemouth bass was 74, higher than the lake's average of 58 (Table 41). Additionally, the RSD 15 value was 45 , which is higher than the lake average of 25 . The largemouth bass population assessment score, based on spring electrofishing data, was "Good", which is an average rating for Herrington Lake (Table 42). Length frequency, relative weight, and index of year class strength at age-0 of largemouth bass based on October 2021 electrofishing data at Herrington Lake are presented in Tables 43-45. Largemouth bass condition $\left(\mathrm{W}_{\mathrm{r}}=93\right)$ was higher than the lake's historic average ( $\mathrm{W}_{\mathrm{r}}=92$; Table 44). Age-0 CPUE for largemouth bass ( $48.7 \mathrm{fish} / \mathrm{hr}$ ) was higher than the lake average ( 34.2 fish $/ \mathrm{hr}$; Table 45). No largemouth bass were stocked in 2021.

Herrington Lake was stocked with 48,227 (20.0 fish/acre; 1.3 in ) reciprocal crossed hybrid striped bass in June 2021.

## Guist Creek Lake (317 acres)

Spring nocturnal electrofishing studies were completed for length frequency, CPUE, and population assessment for largemouth bass in April 2021 (Table 46). The total largemouth bass catch rate ( $154.3 \mathrm{fish} / \mathrm{hr}$ ) was lower than the lake average of 167.6 fish $/ \mathrm{hr}$ (Table 47). The PSD for largemouth bass was 61 compared to the lake average of 66 (Table 48). The $\mathrm{RSD}_{15}$ was 37 compared to the lake average of 40 . The largemouth bass population assessment score, based on spring electrofishing data, was "Excellent", which has been the rating at Guist Creek Lake since 2015 (Table 49). Fall largemouth bass sampling was conducted for length frequency, relative weight, and index of
year class strength at age-0 (Tables 50-52). Relative weight indicated good body condition for bass, especially for bass over 15.0 in (Table 51). The catch rate of age-0 largemouth bass ( $23.7 \mathrm{fish} / \mathrm{hr}$ ) was lower than the lake average (avg. $=44.6$ fish $/ \mathrm{hr}$; Table 52). Largemouth bass were stocked at 14.2 fish/acre ( 4,515 fish ) that averaged 4.0 in at Guist Creek Lake in August 2021. Additionally, largemouth bass removed from Kinman Lake, were stocked at 2.3 fish/acre (740 fish) ranging between 4.0-10.0 in during November 2021.

Saugeye were collected during the spring and fall largemouth bass samples. During the spring sample only one 18.0 -in saugeye was collected for a catch rate of 0.3 fish/hr (Table 46). The fall sample yielded one 8.0 -in saugeye for a catch rate of $0.3 \mathrm{fish} / \mathrm{hr}$ (Table 50). During October, gill nets were used to assess the saugeye population. A total of 7 saugeye were collected from the 19.0 - to 21.0 -in size classes. Age and growth studies indicate saugeye reach the 14.0 -in size limit between age-1 and age-2. Guist Creek Lake was stocked with 31,726 (100.1 fish/acre; 1.5 in ) saugeye in 2021.

Fall gill netting at Guist Creek Lake resulted in two hybrid striped bass (11.0 in and 26.0 in ) being collected. No other data is available due to small sample size. Guist Creek Lake was stocked with 9,566 (30.2 fish/acre; 1.7 in ) reciprocal-cross hybrid striped bass in June 2021.

White crappie, collected during fall gill netting, ranging in size from 6.0 to 9.0 in were used to collect age and growth information. White crappie averaged 7.0 in at age-2 and 8.8 in at age-4.

Guist Creek Lake was stocked with 3,170 (10.0 fish/acre; 7.0 in) channel catfish in June 2021.

## Beaver Lake (158 acres)

A spring diurnal electrofishing sample was completed in April 2021 to assess the black bass population (Table 53). The CPUE for all sizes was 278.0 fish $/ \mathrm{hr}$, greater than the lake average of 259.4 fish $/ \mathrm{hr}$ (Table 54). The PSD and $\mathrm{RSD}_{15}$ for largemouth bass were 32 and 9 , respectively, compared to the lake average of 27 and 4 , respectively (Table 55). The population assessment score indicated an "Excellent" bass population (Table 56), which was above the average assessment rating of "Good" for Beaver Lake. Fall diurnal electrofishing was conducted for relative weight and index age- 0 year class strength of largemouth bass (Tables 57-59). The overall relative weight indicates less than preferred condition $\left(\mathrm{W}_{\mathrm{r}}=85\right)$; the lake average is 85 (Table 58). Fall sampling indicated below average numbers of age- 0 bass, ( 69.3 fish $/ \mathrm{hr}$; average $=139.0 \mathrm{fish} / \mathrm{hr}$ ) and the average size of largemouth bass (4.1 in) was lower than the lake's average of 4.3 in (Table 59). During June an effort was made to reduce the crowded largemouth bass population at Beaver Lake. Seven hundred and twenty-two (4.6 fish/acre) largemouth bass were removed from Beaver Lake in 2021. Largemouth bass removed ranged in size from 4.0 to 11.0 in ( $<8.0$ in $=336$ (46.5\%); 8.0-10.9 in = 295 ( $40.9 \%$ ); 11.0 in = 91 (12.6\%)).

Fall diurnal electrofishing was completed in October 2021 for age and growth and relative weight for panfish populations at Beaver Lake (Tables 60-62). Age and growth studies indicated bluegill averaged 6.0 in between age3 and age-4 (Table 60). Redear sunfish averaged 8.0 in between age-2 and age-3 (Table 61). Overall, relative weight data for bluegill was fair while the body condition of redear sunfish was good (Table 62). Redear sunfish (31,600 fish; 200.0 fish/acre) were stocked in September 2021 at an average size of 1.6 in .

Channel catfish were sampled in December 2021 using tandem hoop nets. Length frequency results for channel catfish showed a size distribution between the 11.0- and 23.0-in size class (Table 63). PSD and RSD 24 were 20 and 0 , respectively (Table 64). Relative weight indicated good body condition for channel catfish ( $\mathrm{W}_{\mathrm{r}}=92$; Table 65). Overall, catch rates at Beaver Lake in 2021 ( 35.4 fish/set) remained slightly lower than the lake average of 41.8 fish/set (Table 66). Channel catfish stocking has been temporarily suspended to install spawning boxes in spring 2022 to determine their affects to the channel catfish population in Beaver Lake.

In May, 675 lbs of granular 10-52-4 fertilizer was applied in Beaver Lake. Three applications of aquatic herbicides were applied in June and September of 2021 to maintain the bank fishing areas, boat ramp, and fishing pier at Beaver Lake.

Ten rock piles (reefs) were constructed at Beaver Lake using 96 tons of shot rock.

## Benjy Kinman Lake ( 88 acres)

A spring nocturnal electrofishing sample was completed in April 2021 at Benjy Kinman Lake to assess the black bass population (Table 67). The CPUE for all sizes was 263.5 fish $/ \mathrm{hr}$, compared to the lake average of $162.2 \mathrm{fish} / \mathrm{hr}$ (Table 68). The PSD and RSD $_{15}$ for largemouth bass were 11 and 7, respectively (Table 69). The population assessment score indicated a "Fair" bass population (Table 70). Fall largemouth bass sampling was conducted for relative weight, age and growth, and index of year class strength at age-0 in September 2021 (Tables 71-74). Overall, relative weight indicated below average body condition for bass ( $\mathrm{W}_{\mathrm{r}}=87$ ) with larger fish exhibiting better condition compared to smaller length groups (Table 72). The better condition of larger fish is due to the gizzard shad forage base. Age and growth studies on largemouth bass show largemouth bass are growing to 12.0 in between age- 3 and age-4 (Table 73). Fall sampling indicated above average numbers of age-0 bass, ( $100.7 \mathrm{fish} / \mathrm{hr}$; average $=79.1 \mathrm{fish} / \mathrm{hr}$ ) and the average size of largemouth bass ( 4.6 in ) was equal to lake's average of 4.6 in (Table 74). During November, an effort was made to reduce the crowded largemouth bass population at Benjy Kinman Lake. Seven hundred and forty ( 8.4 fish/acre) largemouth bass were removed from Benjy Kinman Lake and stocked into Guist Creek Lake. Largemouth bass removed ranged in size from 4.0 to 10.0 in ( $<8.0$ in $=290$ (39.2\%); 8.0-10.9 in $=450(60.8 \%)$ ).

Relative weight for bluegill and redear sunfish were collected during the fall bass sample at Benjy Kinman Lake (Table 75). Overall, relative weight for panfish were acceptable.

A diurnal electrofishing study to evaluate the crappie population was completed in October 2021. A total of 26 crappie ( 3 white crappie and 23 black crappie) were collected in 1.5 hrs of electrofishing (Table 76). Age and growth assessment of black crappie indicated they reach 9.0 in between age-4 and age-5 (Table 77). Age and growth assessment is not reported on white crappie due to a low sample size. Relative weight indicated below average body condition for white crappie $\left(\mathrm{W}_{\mathrm{r}}=81\right)$ and acceptable condition for black crappie $\left(\mathrm{W}_{\mathrm{r}}=92\right.$; Table 78).

Channel catfish were sampled in December 2021 using tandem hoop nets. Length frequency results for channel catfish showed a size distribution between the 11.0- and 24.0-in size class (Table 79). PSD and RSD 24 were 86 and 14 , respectively (Table 80). Overall, catch rate ( 1.4 fish/set) in 2021 was lower than the historic average of 8.0 fish/set (Table 81). Relative weight indicated good body condition for channel catfish ( $\mathrm{W}_{\mathrm{r}}=96$, Table 82). In 2020, 15 wooden catfish spawning boxes were installed to promote channel catfish spawning. These boxes were monitored for usage in 2021. All boxes were evaluated for usage weekly beginning on June $7^{\text {th }}$ and were observed through June $29^{\text {th }}$. Of the 15 boxes, fish were observed using eight $(53.3 \%)$ of these boxes in 2021 . This was an increase from only two (13.3\%) boxes used in 2020. Spawning activity was observed in five different boxes, with one box recording multiple spawns. One box was observed with a spawning pair, four boxes with adult catfishes and eggs, and one box with an adult catfish and fry.

Ten rough fish removal events took place from March 2021 - December 2021 resulting in a total of 185 bigmouth buffalo, smallmouth buffalo, grass carp, silver carp, common carp, freshwater drum, and longnose gar being removed from Benjy Kinman Lake. The average weight of rough fish removed in 2021 was 10.0 lbs . Therefore, it was estimated that $1,850 \mathrm{lbs}$ of rough fish were removed. The eight-year total for rough fish removed from Benjy Kinman Lake is 4,417 fish ( 50.2 fish/acre) at an estimated weight of $34,342 \mathrm{lbs}$ ( $390.3 \mathrm{lbs} / \mathrm{acre}$ ). The slight increase in the numbers of rough fish, plus additional species, was due to the Kentucky River flooding Benjy Kinman Lake in the late winter/early spring of 2021.

Three hundred and fifty pounds of granular fertilizer (10-52-4) was applied in May 2021 at Benjy Kinman Lake.
Water willow collected from the spillway at McNeely Lake was transplanted into Benjy Kinman Lake to create 4 new water willow beds during the summer 2021.

## Boltz Lake (92 acres)

Spring nocturnal electrofishing was completed in April 2021 to assess the black bass population (Table 83). Results indicated the largemouth bass catch rate ( 188.5 fish $/ \mathrm{hr}$ ) was slightly lower than the lake's historic average (192.7 fish $/ \mathrm{hr}$; Table 84). The PSD for largemouth bass was 62 compared to the lake average of 45 (Table 85 ). The RSD 15 was 23 , higher than the lake average of 17 . The population assessment indicated a "Good" bass population (Table 86). Fall diurnal electrofishing was conducted for relative weight and index of age-0 year class strength in October 2021 (Tables 87-89). Relative weight indicated acceptable body condition ( $\mathrm{W}_{\mathrm{r}}=92$ ), higher than the lake's average relative weight of 90 (Table 88). Fall sampling indicated above average numbers of age-0 bass, ( 250.0 fish $/ \mathrm{hr}$; average $=79.2 \mathrm{fish} / \mathrm{hr}$ ) and the average size ( 3.9 in ) was smaller than the lake's historic average size of 4.2 in (Table 89). No bass were stocked into Boltz Lake in 2021.

Saugeye were collected during the spring largemouth bass sample in April 2021 (Table 83). A total of 5 saugeye were collected at 2.5 fish $/ \mathrm{hr}$ ranging in size from the 8.0 - to 21.0 -in size class. Saugeye were collected during fall largemouth bass sampling at a rate of 6.7 fish/hr with fish ranging between the 19.0- and 25-in size class (Table 87). Saugeye were not stocked into Boltz Lake in 2021. The next planned stocking will be in 2023.

Relative weight data for bluegill and redear sunfish was collected during the fall bass sample at Boltz Lake (Table $90)$. The relative weight index reflected acceptable body condition for both bluegill $\left(\mathrm{W}_{\mathrm{r}}=92\right)$ and redear sunfish ( $\mathrm{W}_{\mathrm{r}}=101$ ).

Diurnal electrofishing studies to evaluate the crappie population were completed in October 2021. A total of 43 white crappie were collected in 1.25 hrs of electrofishing (Table 91). Age and growth studies indicated that white crappie generally reach 9.0 in between age-2 and age-3 (Table 92). Relative weights indicated a slightly below average body condition for white crappie $\left(\mathrm{W}_{\mathrm{r}}=89\right.$; Table 93).

Boltz Lake was stocked with 2,160 (23.5 fish/acre; 7.0 in) channel catfish in June 2021.

## Bullock Pen Lake (134 acres)

Spring diurnal electrofishing was completed in April 2021 to assess the black bass population (Table 94). The total catch rate of largemouth bass ( $265.0 \mathrm{fish} / \mathrm{hr}$ ) was higher than the lake's average catch rate of $153.6 \mathrm{fish} / \mathrm{hr}$ (Table 95). The PSD for largemouth bass was 47 , lower than the lake average of 69 (Table 96). The RSD 15 for largemouth bass was 24 , lower than the lake average of 39 . The population assessment for largemouth bass was rated "Excellent"; which is better than the lake's average rating of "Good" (Table 97). Fall diurnal electrofishing was conducted in September 2021 to determine length frequency, relative weight, and index of age- 0 year class strength for largemouth bass (Tables 98-100). Relative weight indicated acceptable body condition for bass ( $\mathrm{W}_{\mathrm{r}}=90$ ) but was lower than the lake's average ( $\mathrm{W}_{\mathrm{r}}=93$; Table 99). Larger fish exhibited better condition compared to smaller length groups, which is a function of the shad forage base. Age-0 CPUE ( 16.0 fish $/ \mathrm{hr}$ ) was lower than the lake average ( 22.9 fish $/ \mathrm{hr)}$; however, no largemouth bass were stocked in 2021 (Table 100).

Saugeye were collected during the spring and fall largemouth bass samples. Five saugeye were collected during the spring sample at 2.5 fish $/ \mathrm{hr}$ between the 14.0 - and 25.0 -in size classes (Table 94). Six saugeye ( $4.0 \mathrm{fish} / \mathrm{hr}$ ) were collected in September 2021 between the 17.0- and 26.0-in size classes (Table 98). Bullock Pen Lake was stocked with 13,543 (101.1 fish/acre; 1.6 in ) saugeye in May 2021.

Bullock Pen Lake was stocked with 2,430 (18.1 fish/acre; 7.0 in) channel catfish in June 2021.

## Corinth Lake (96 acres)

Spring nocturnal electrofishing was completed in April 2021 to assess the black bass population (Table 101). The total catch rate of largemouth bass ( 302.0 fish $/ \mathrm{hr}$ ) was higher than the lake's average catch rate of $248.8 \mathrm{fish} / \mathrm{hr}$ (Table 102). The PSD for largemouth bass was 36, higher than the lake average of 23 (Table 103). The RSD 15 for largemouth bass was 9 , higher than the lake average of 7 . The population assessment for largemouth bass was rated
"Good"; the average rating since 2005 (Table 104). Fall diurnal electrofishing for largemouth bass was conducted to determine length frequency, relative weight, and index of year class strength at age-0 (Tables 105-107). Relative weight of largemouth bass continues to be below average across the 8.0 - to 11.9-in and 12.0- to 14.9 -in length groups. The overall relative weight in $2021\left(\mathrm{~W}_{\mathrm{r}}=82\right)$ was lower than the historic average at Corinth Lake $\left(\mathrm{W}_{\mathrm{r}}=84\right.$; Table 106). Age-0 CPUE ( $85.3 \mathrm{fish} / \mathrm{hr}$ ) was lower than the lake average ( $87.4 \mathrm{fish} / \mathrm{hr}$ ); however, no largemouth bass were stocked in 2021 (Table 107).

Fall diurnal electrofishing for bluegill and redear sunfish was conducted for relative weight. Relative weight indicated fair condition for bluegill (89) and good condition for redear sunfish (95; Table 108).

Corinth Lake was stocked with 1,945 (20.3 fish/acre; 7.0 in) channel catfish in June 2021.
In May 2021, 70 gallons of 9-18-9 fertilizer was applied at Corinth Lake.

## Elmer Davis Lake (149 acres)

Spring diurnal electrofishing studies were conducted in April 2021 for length frequency, PSD and CPUE for largemouth bass (Table 109). The total catch rate ( 270.5 fish $/ \mathrm{hr}$ ) was lower than the historical lake average of 305.3 fish $/ \mathrm{hr}$ (Table 110). Largemouth bass PSD and $\mathrm{RSD}_{15}$ were 30 (average $=33$ ) and 6 (average $=8$ ), respectively (Table 111). The population assessment indicated a "Good" bass population, which has been the average rating since 2004 (Table 112). Fall electrofishing for largemouth bass was completed to evaluated age and growth, relative weight, and index of year class strength at age-0 (Tables 113-115). Largemouth bass relative weight ( $\mathrm{W}_{\mathrm{r}}=87$ ) was equal to the historical lake average $\left(\mathrm{W}_{\mathrm{r}}=87\right.$; Table 114). The year class strength model indicated that 2021 was below average for young-of-year largemouth bass. Age-0 CPUE ( 91.3 fish $/ \mathrm{hr}$ ) was lower than the lake average (140.1 fish/hr; Table 115). No largemouth bass were stocked during 2021.

Diurnal spring electrofishing for length frequency, CPUE, and population assessment data was conducted for bluegill and redear sunfish in May 2021 (Tables 116). The total bluegill catch rate ( $293.6 \mathrm{fish} / \mathrm{hr}$ ) remains higher than the lake average of 255.3 fish/hr (Table 117). The PSD value for bluegill (42) was higher than the lake average of 34 (Table 118). The $\mathrm{RSD}_{8}$ (7) was higher than the lake average of 3. The population assessment for bluegill was "Excellent" (Table 119). The total catch rate of redear sunfish ( 56.8 fish $/ \mathrm{hr}$ ) was lower than the lake average of 69.5 fish $/ \mathrm{hr}$ (Table 120). The PSD for redear sunfish was 63 compared to the lake average of 58 . The RSD 9 was 31 compared to the lake average of 20 (Table 118). The redear sunfish population assessment indicated an "Excellent" population, which is the highest rating since 2013 (Table 121). Age and growth results indicate that bluegill reach 6.0 in between age- 2 and age- 3 (Table 122). Redear sunfish reach 8.0 in between age- 2 and age- 3 (Table 123). Relative weight index reflects good condition for both bluegill ( $\mathrm{W}_{\mathrm{r}}=93$ ) and redear sunfish ( $\mathrm{W}_{\mathrm{r}}=101$; Table 124). Elmer Davis Lake was stocked with 3,000 (20.1 fish/acre) redear sunfish in September 2021.

Channel catfish were sampled on 6 and 9 December 2021 using tandem hoop nets. Length frequency results for channel catfish showed a size distribution between the 17.0 - and 27.0 -in size classes (Table 125). PSD and RSD 24 were 100 and 41 , respectively (Table 127). Relative weight indicated excellent body condition for channel catfish $\left(\mathrm{W}_{\mathrm{r}}=104\right.$; Table 128). In May 2021, 25 wooden catfish spawning boxes were installed to promote spawning. Three spawning boxes were missing at the first usage evaluation and were not replaced until the end of the evaluation period. Therefore, only 22 boxes were part of the weekly usage evaluation from June $7^{\text {th }}$ through June $28^{\text {th }}$. Of the 22 boxes, fish were observed using 16 of them. Eleven boxes were observed with adult fish guarding an egg mass, one box recorded multiple spawns, and one box was observed with an adult catfish and fry.

Time-lapse cameras were installed at two boat ramp access areas at Elmer Davis Lake from March 2021- February 2022 to estimate total usage (trips) and pressure (hours) at this public access area. This approach differs from previous daytime roving creel surveys in that these counts capture all usage types (boat anglers, bank anglers, and recreational boaters). However, the primary usage of these sites was by anglers. The time-lapse camera recorded a picture of the entire fishing area (parking lot and boat ramp) every 10 -minutes during daylight hours throughout the study period. Images were analyzed by randomly selecting 16 days ( 10 week and 6 weekend days) each month, which included an a.m. or p.m. period. During those selected dates and times, individual vehicles were selected for each fishing type (trailered boat, carry-down boat, bank), party size per vehicle and total trip lengths were recorded.

A total individual vehicle count was also collected for the entire day. From these counts, monthly averages were calculated.

Overall, it was estimated that 6,482 trips ( 43.5 trips/acre) were taken to Elmer Davis Lake from March 2021February 2022 (Table 129). Monthly trip totals ranged from 6 trips in January 2022 to 1,484 trips in May 2021 (Figure 1). Overall, the average trip length for the year was 3.0 hours. Average trip lengths ranged from 1.2 hours in February 2022 to 4.3 hours in April 2021. May ( 5,668 hours) and June ( 4,029 hours) recorded the highest usage rates (Figure 2). It was estimated that Elmer Davis Lake received 23,046 hours (154.7 hours/acre) of recreational pressure during this 12 -month study period (Table 129).

## Kincaid Lake (183 acres)

Spring diurnal electrofishing studies were conducted in May 2021 for length frequency, PSD, and CPUE for largemouth bass (Table 130). Total catch rate ( $229.0 \mathrm{fish} / \mathrm{hr}$ ) was above the lake average of $215.4 \mathrm{fish} / \mathrm{hr}$ (Table 131). Largemouth bass PSD and $\mathrm{RSD}_{15}$ were 63 (average $=68$ ) and 43 (average $=45$ ), respectively (Table 132). The population assessment indicated an "Excellent" bass population, which is above the average assessment rating of "Good" at Kincaid Lake (Table 133). Diurnal fall electrofishing for largemouth bass in October 2021 was completed to collect length frequency, age and growth, relative weight, and index year class strength at age-0 (Tables 134-137). Growth rates at Kincaid Lake indicated that largemouth bass reach harvestable size (12.0 in) between age-3 and age-4 (Table 135). Additionally, largemouth bass reach 15.0 in at age-5. Relative weight was acceptable $\left(\mathrm{W}_{\mathrm{r}}=92\right)$ and equal to the lake's average (Table 136). CPUE for age-0 bass ( $20.0 \mathrm{fish} / \mathrm{hr}$ ) was lower than the lake average of 37.9 fish $/ \mathrm{hr}$ (Table 137). However, no largemouth bass were stocked in Kincaid Lake in 2021.

Kincaid Lake was stocked with 2,200 (12.0 fish/acre; 7.0 in) channel catfish in June 2021.

## McNeely Lake (51 acres)

Diurnal fall electrofishing for largemouth bass in October 2021 was completed to collect length frequency, relative weight, and index year class strength at age-0 (Table 138-140). Relative weight (87) was less than the lake average $\left(\mathrm{W}_{\mathrm{r}}=89\right.$; Table 139). CPUE for age-0 bass (132.0 fish/hr) was higher than the lake average of $123.6 \mathrm{fish} / \mathrm{hr}$ (Table 140).

Bluegill and redear sunfish were sampled in May 2021 for length frequency, CPUE, and population assessment (Table 141). The bluegill PSD was 43, equal to the lake average (Table 142). $\mathrm{RSD}_{8}$ was 0 , compared to the lake average of 1. Catch rate for bluegill ( 428.8 fish $/ \mathrm{hr}$ ) was higher than the lake average catch rate of $341.3 \mathrm{fish} / \mathrm{hr}$ (Table 143). The population assessment rating for bluegill was "Good" (Table 144). The total catch rate for redear sunfish ( 83.2 fish $/ \mathrm{hr}$ ) was higher than the lake average ( $62.8 \mathrm{fish} / \mathrm{hr}$; Table 145). The PSD for redear sunfish was 62 compared to the lake average of 50 and the $\mathrm{RSD}_{9}$ was 4 compared to the lake average of 7 (Table 142). The redear sunfish population assessment rated this fishery as "Good" in 2021 (Table 146). Age and growth and relative weight for bluegill and redear sunfish were collected during the fall diurnal electrofishing sample. Age and growth studies show that bluegill continue to reach 6.0 in around age- 3 (Table 147). Redear sunfish reach 8.0 in between age-3 and age-4 (Table 148). Overall, conditions for both bluegill (90) and redear sunfish (95) were acceptable (Table 149).

McNeely Lake was stocked with 1,275 (25.0 fish/acre; 7.0 in ) channel catfish in October 2021.

## Doe Run Lake (49 acres)

Relative abundance and CPUE of fish collected at Doe Run Lake in May 2021 are shown in Table 150. Largemouth bass were collected from the 2.0 - to 20.0 -in size classes. Bluegill were collected up to the 7.0 -in size class. White crappie and channel catfish were also collected during this sample. Doe Run Lake has an abundant population of common carp and gizzard shad.

## Kentucky River WMA (Boone Tract: Prather Pond, 6-acre pond and 15-acre pond)

## Prather Pond (4 acres)

Length frequency, relative abundance, and CPUE of fishes collected in June 2021 by electrofishing at Prather Pond are shown in Table 151. Largemouth bass were collected from the 4.0- to 18.0-in size classes. Bluegill and redear sunfish were collected up to the 7.0 -in and 8.0 -in size classes, respectively. Crappie were also collected. During the sample, gizzard shad were observed which indicates the rotenone treatment completed in December 2020 was unsuccessful.

On May 1, 2021, twenty-five pounds of granular Aquathol Super K was used to treat curly-leafed pondweed in Prather Pond.

## Boone Tract 6-acre pond

Length frequency, relative abundance, and CPUE of fishes collected in June 2021 by electrofishing at the Boone Tract 6 -acre pond are shown in Table 152. Largemouth bass were collected from the 5.0 - to 13.0 -in size classes. Bluegill were collected up to the 8.0 -in size class. Redear sunfish, black crappie, and channel catfish were also collected. No gizzard shad were collected or observed during this survey indicating positive results from the rotenone treatment completed in December 2020.

During February and October 2021, a total of 2,000 rainbow trout were stocked averaging 10.0 in to provide a put and take winter fishing opportunity.

## Boone Tract $\mathbf{1 5 - a c r e}$ pond

Length frequency, relative abundance, and CPUE of fishes collected in June 2021 by electrofishing at the Boone Tract 15-acre pond are shown in Table 153. Largemouth bass were collected from the 4.0 - to 15.0in size classes. Bluegill were collected up to the 8.0 -in size class. Redear sunfish and black crappie were also collected.

## Kleber WMA Pond (3 acres)

Length frequency, relative abundance, and CPUE of fish collected by electrofishing at Kleber WMA Pond (Owen Co.) in September 2021 are shown in Table 154. Largemouth bass were collected from the 4.0 - to 13.0 -in size class. Bluegill and redear sunfish were collected up to the 7.0 -in and 8.0 -in size classes, respectively. Black crappie and channel catfish were also represented in the sample.

Kleber WMA Pond was stocked with 150 ( 50.0 fish/acre) channel catfish in October 2021.

## Lincoln Homestead Lake (9 acres)

Length frequency, relative abundance and CPUE of fish collected by electrofishing at Lincoln Homestead Lake (Washington Co.) in May 2021 are shown in Table 155. Largemouth bass were collected from the 5.0- to 19.0-in size classes and bluegill up to the 9.0 -in size class. Trophy size ( $\geq 10.0$ in) redear sunfish were sampled. White crappie were also represented in the sample.

## Long Run Park Lake (27 acres)

Length frequency, relative abundance and CPUE of fish collected by electrofishing at Long Run Park Lake (Jefferson Co.) in November 2021 are shown in Table 156. Largemouth bass were collected from the 3.0- to 19.0-in size classes. Both bluegill and redear sunfish were collected up to the 8.0 -in size class. Black crappie were represented in the sample.

## Reformatory Lake (54 acres)

Length frequency, relative abundance and CPUE of fish collected by electrofishing at Reformatory Lake (Oldham Co.) in May 2021 are shown in Table 157. Largemouth bass were collected from the 3.0 - to 20.0 -in size classes, bluegill from the $1.0-$ to 7.0 -in size classes, and redear sunfish from the $1.0-$ to $10.0-\mathrm{in}$ size classes. Other species observed included white crappie, black crappie, yellow bass, channel catfish, and flathead catfish.

Reformatory Lake was stocked with 1,090 (20.2 fish/acre) channel catfish in June 2021.

## Sympson Lake (127 acres)

Relative abundance and CPUE of largemouth bass collected in April 2021 are shown in Table 158. Largemouth bass were collected from the 3.0 - to 20.0 -in size classes. Good numbers of bass were present above the 15.0 -in size limit. Good numbers and size distribution of white crappie was observed during this sample. An abundant population of common carp are also present in the lake.

Sympson Lake was stocked with 1,910 (15.0 fish/acre) channel catfish in June 2021.

## Thurman Hutchins Lake (2 acres)

Length frequency, relative abundance, and CPUE of fish collected by electrofishing at Thurman Hutchins Lake (Jefferson Co.) in November 2021 are shown in Table 159. Largemouth bass were collected from the 4.0- to 19.0-in size classes. Majority of the bluegill collected were in the 6.0 - to 7.0 -in size classes, with redear sunfish collected up to the 10.0 -in size class. Other species collected included white and black crappie.

## Veterans WMA Pond (3 acres)

Length frequency, relative abundance, and CPUE of fish collected by electrofishing at Veterans WMA Pond (Scott Co.) in September 2021 are shown in Table 160. Largemouth bass were collected from the 4.0 - to 22.0 -in size classes. Bluegill were collected up to the 8.0 in size class with good numbers greater than 6.0 in . No other species were collected.

## Willisburg Lake (126 acres)

Relative abundance and CPUE of largemouth bass collected in April 2021 are shown in Table 161. Largemouth bass were collected from the 2.0 - to 20.0 -in size classes. Good numbers of bass were present above the 12.0 -in size limit.

## $\underline{\text { Willisburg Pond (1 acre) }}$

Length frequency, relative abundance, and CPUE of fish collected by electrofishing at Willisburg Pond (Washington Co.) in June 2021 are shown in Table 162. Largemouth bass were collected from the 13.0 - to 18.0 -in size class. Bluegill were collected up to the 6.0 -in size class. Channel catfish was the only other species collected in this sample.

Largemouth bass, removed from Beaver Lake, were stocked at 55.0 fish/acre ( 55 fish) ranging between the 3.0 -in and 10.0-in size classes in September 2021.

Willisburg Pond was stocked with 50 ( 50.0 fish/acre; 7.25 in) channel catfish in June 2021.

# Elmer Davis Lake Angler Attitude Survey 2021 

(based on 34 surveys)

1. On average how many times do you fish at Elmer Davis Lake in a year? ( $\mathrm{n}=34$ )
First time: 8.8\%
1 to 4: 20.6\%
5 to 10: 11.8\%
More than 10: 58.8\%
2. Which species of fish do you fish for at Elmer Davis Lake (circle all that apply)? ( $\mathrm{n}=34$ )

Bass 29.4\% Crappie 50.0\% Bluegill 76.5\% Redear Sunfish 38.2\% Catfish 8.8\% Other 0.0\%
3. Which one species do you fish for the most at Elmer Davis Lake (circle only one)? ( $\mathrm{n}=222$ ) Bass 14.7\% Crappie 8.8\% Bluegill 61.8\% Redear Sunfish 8.8\% Catfish 5.9\% Other 0.0\%
-Answer the following questions for each species you fish for - (see question 2)

## Bass Anglers

4. In general, what level of satisfaction or dissatisfaction do you have with bass fishing at Elmer Davis Lake? ( $\mathrm{n}=9$ )
Very satisfied 11.1\% Somewhat satisfied 33.3\% Neutral 33.3\% Somewhat dissatisfied 22.3\% Very dissatisfied 0.0\%

4a. If you responded with very or somewhat satisfied in question (4) - What is the single most important reason for your Satisfaction? ( $\mathrm{n}=4$ )
Number of fish 25.0\% Size of fish 75.0\%
4b. If you responded with somewhat or very dissatisfied in question (4) - What is the single most important reason for your Dissatisfaction? ( $n=2$ )
Number of fish 100.0\%

## Crappie Anglers

5. In general, what level of satisfaction or dissatisfaction do you have with crappie fishing at Elmer Davis Lake? ( $\mathrm{n}=17$ )
Very satisfied 17.6\% Somewhat satisfied 17.6\% Neutral 17.6\% Somewhat dissatisfied 47.2\%
Very dissatisfied 0.0\%
5a. If you responded with very or somewhat satisfied in question (5) - What is the single most important reason for your Satisfaction? ( $n=6$ ) Number of fish 50.0\% Size of fish 50.0\%

5b. If you responded with somewhat or very dissatisfied in question (5) - What is the single most important reason for your Dissatisfaction? ( $n=8$ )
Number of fish 100.0\%

## Bluegill Anglers

6. In general, what level of satisfaction or dissatisfaction do you have with bluegill fishing at Elmer Davis Lake? ( $\mathrm{n}=26$ )
Very satisfied 57.7\% Somewhat satisfied 23.1\% Neutral 7.7\% Somewhat dissatisfied 11.5\%
Very dissatisfied 0.0\%
6a. If you responded with very or somewhat satisfied in question (6) - What is the single most important reason for your Satisfaction? ( $n=21$ )
Number of fish 23.8\% Size of fish 76.2\%
6b. If you responded with somewhat or very dissatisfied in question (6) - What is the single most important reason for your Dissatisfaction? ( $n=3$ )
Number of fish 33.3\% Size of fish 66.7\%

## Redear Sunfish Anglers

7. In general, what level of satisfaction or dissatisfaction do you have with redear sunfish fishing at Elmer Davis Lake? ( $\mathrm{n}=12$ )
Very satisfied 66.7\% Somewhat satisfied 8.3\% Neutral 0.0\% Somewhat dissatisfied 25.0\% Very dissatisfied 0.0\%

7a. If you responded with very or somewhat satisfied in question (7) - What is the single most important reason for your Satisfaction? ( $n=9$ ) Size of fish 100.0\%

7b. If you responded with somewhat or very dissatisfied in question (7) - What is the single most important reason for your Dissatisfaction? $(\mathrm{n}=3)$
Number of fish 33.3\% Size of fish 66.7\%

## Catfish Anglers

8. In general, what level of satisfaction or dissatisfaction do you have with catfish fishing at Elmer Davis Lake? ( $\mathrm{n}=3$ )
Very satisfied 0.0\% Somewhat satisfied 33.3\% Neutral 33.4\% Somewhat dissatisfied 0.0\% Very dissatisfied 33.3\%

8a. If you responded with very or somewhat satisfied in question (8) - What is the single most important reason for your Satisfaction? ( $n=1$ ) Size of fish 100.0\%

8b. If you responded with somewhat or very dissatisfied in question (8) - What is the single most important reason for your Dissatisfaction? ( $n=1$ ) Number of fish 100.0\%

## All Anglers

9. In general, are you satisfied with the current size and creel limits at Elmer Davis Lake? ( $\mathrm{n}=33$ ) Yes 97.0\% No 3.0\%

9a. If "no", which species are you dissatisfied with and what size and creel limits would you prefer? Largemouth bass minimum size limit ( $n=1$ )
10. In the past 12 months, have you harvested largemouth bass under the 12-15-inch slot limit? ( $\mathrm{n}=32$ ) Yes 75.0\% No 25.0\%
11. In general, what level of satisfaction or dissatisfaction do you have with the current facilities (parking lot, boat ramp, fishing pier, courtesy dock) at Elmer Davis Lake? ( $n=34$ ) Very satisfied 76.5\% Somewhat satisfied 17.6\% Neutral 0.0\% Somewhat dissatisfied 5.9\% Very dissatisfied 0.0\%

11a. If you responded with somewhat or very dissatisfied in question (12) - What is the single most important reason for your Dissatisfaction? ( $n=2$ ) Need toilet at dam ramp 50.0\% Need security light on dam ramp 50.0\%

Table 130. Species composition, relative abundance, and CPUE (fish/hr) of black bass collected in 2.0 hours of 15 -minute electrofishing runs in Kincaid Lake, May 2021; numbers in parentheses are standard errors.

# NORTHEASTERN FISHERY DISTRICT 

Project 1: Lake and Tailwaters Fishery Surveys

## FINDINGS

All sampling conditions can be found in Table 1.

## Cave Run Lake (8,720a)

## Muskellunge sampling

Due to high water and high discharge events at optimal sampling times the lake was not sampled in 2021 for muskellunge. This is reflected in the lake assessment table (Table 2).

## Black bass sampling (Spring)

On April 26-27 and 03 May, the upper, middle, and lower sections of Cave Run Lake were nocturnally electrofished for assessment of the black bass population. In total, 1,422 fish were captured. The majority of these fish were largemouth bass ( $71 \%$ ), followed by spotted bass ( $28 \%$ ) and smallmouth bass ( $1 \%$; Table 3 ). As is normally the case, the percentage of the population represented by spotted and smallmouth bass increases as you head from the upper sections of the lake to the lower sections of the lake. Catch rates were higher than the 1990-2020 average for largemouth bass less than 8.0 in, as well as in the 8.0 - to 11.9 -in, over 15.0 -in, and over 20.0 -in ranges (Table 4). Catch rates of the larger fish continue to be better now than the pre-slot limit time periods. PSD and RSD 15 values for largemouth bass demonstrate that most of the fish in the lake are below 12.0 in and that there is an even spread of this small fish abundance across lake areas (Table 5). Overall, the largemouth bass population was rated as "good" (Table 6) and the spotted bass population was rated as "fair" (Table 7). It should be noted, however, that the parameter "Spring CPUE age-1" continues to be debilitatingly high for largemouth bass.

## Grayson Lake (1,512a)

## Black bass sampling (Spring/Fall)

The black bass population of Grayson Lake was nocturnally electrofished on $19-21$ of April. In total, 1,169 fish were collected ranging in size from 3.0 to 21.0 in (Table 8). Most of these fish ( $85 \%$ ) were largemouth bass and the remainder were spotted bass ( $15 \%$ ). Catch rates by length group were higher than the average from 1999-2020 except for fish in the 12.0 - to 14.9 -in range which were slightly lower (Table 9). Of those largemouth bass over 8.0 in, the majority were under 12.0 in as demonstrated by PSD values. In addition, the upper portions of the lake have a higher ratio of larger fish to smaller fish (although the upper section also produced the lowest catch rates of fish overall; Table 10). In September, a subsample of fish from each in class was sacrificed for determination of age and growth characteristics. This analysis showed that there is potential for fish to reach 15.0 inches in their third year, but on average it takes 5 or 6 years to hit this mark (Table 11). This subsample of fish was equally collected from each section of the lake to determine if there were potential differences. This analysis showed similar results regardless of area of the lake (Table 12). Lastly, this same data was further broken down to look for differences between the sexes. This analysis showed similar results between males and females until age- 5 when the females begin to show a higher growth rate (Table 13). Combining this age and growth data with the spring sampling data gives a 2021 assessment of "fair" for Grayson Lake largemouth bass (Table 14).

While collecting fish for age and growth in September, data was also collected to determine relative weights and spawning strength of largemouth bass in Grayson Lake. From $27-29$ September, 1,198 fish were collected (Table 15). Overall, relative weights were in the middle 70 's to 80 's range (Table 16). Larger fish seemed to exhibit better growth but were caught in far lower numbers. Indices of year class strength for largemouth bass continue to be on the high end (Table 17) and the lake was once again not stocked with young of year largemouth bass in 2021.

## Creel Survey

From 01 April to 31 October, a roving creel survey was conducted on Grayson Lake. There were over 18,000 angling trips made on the lake during this time (Table 18). While the number of trips was much higher than previous years, all catch rate parameters (fish per hour and fish per acre) as well as harvest rate parameters (fish per
hour, fish per acre, and pounds per acre) were all similar to previous years. This showed that trends remained similar year to year. As in previous years, most anglers were casting male residents fishing from a boat. Crappie made up most of the fish caught $(45,391.5)$, followed by black bass $(41,858.1)$ and panfish $(17,075.6$; Table 19). Most of the trips made on Grayson Lake were for black bass ( $48.4 \%$ ), followed by crappie ( $14.2 \%$ ) and panfish ( $5.3 \%$ ). Table 20 shows the number of fish harvested and released by in class. As has been the case in previous years, almost every largemouth bass caught is released ( $<1 \%$ harvested overall, $2.6 \%$ harvest rate of legal ( $\geq 15.0 \mathrm{in}$ ) fish). Crappie anglers harvest rates of fish under 9.0 in were less than $50 \%$ but over 9.0 -in harvest rates picked up to well above $50 \%$ (this is the case for both black and white crappie). The best months for largemouth bass fishing are May, June, and September (Table 21). The best months for crappie fishing were April and May (Table 22). The best months for catfish angling were May and August (Table 23).

## Angler Attitude Survey

In conjunction with the creel survey, anglers were asked a series of questions pertaining to their attitudes towards fishing on Grayson Lake (Table 24). As has been the case in previous years the most fished for species were bass and crappie and most of those anglers are satisfied with their fishing experience. The majority of catfish anglers utilized hook and line as their primary method (followed by jug fishing, hand fishing, and limb or trot lines) and overall, catfish anglers were satisfied with their angling experience. Similarly, hybrid striped bass anglers were overall happy with their experiences. When ranking largemouth bass regulation options, more anglers opposed the concept of a 12 -in minimum size limit ( $27.1 \%$ opposed) followed by a 15 -in minimum size limit ( $18.6 \%$ opposed), and a slot limit ( $16.3 \%$ opposed). Although it should be noted that most of the anglers support any regulation; meaning similar numbers of folks' support or oppose any regulation that might be imposed. Most anglers rate the existing habitat on the lake as good and those that fish department-placed habitat have good experiences with it.

## Lake Carnico (114a)

## Black bass sampling (Fall)

On 27 September, Lake Carnico was diurnally electrofished to assess the fish population. In total, 100 largemouth bass were collected ranging from 2.0 to 18.0 in (Table 25). This sampling effort was used to collect fish for assessment of relative weights and age and growth. Relative weights were all in the upper 80's to lower 90's for the population as a whole and for each size range (Table 26). The subsample of fish used to determine age and growth characteristics showed that fish could reach 15.0 in by their $4^{\text {th }}$ year but most took 5 years (Table 27). This age and growth analysis also gave a mean length of 11.8 in for age- 3 fish in the spring which can be rated as excellent when compared to lakes of similar sizes (Table 28).

## Saugeye

On 02 and 03 of November, Lake Carnico was gill netted (150', 5 panel gill nets) and on 08 November the lake was nocturnally electrofished ( 6,15 -minute sampling runs on DC low, 60 pulses per second ( pps ) and 3-4 amps) for an assessment of the saugeye population and comparison of sampling techniques. Gill netting captured 23 fish across 2 nights and electrofishing captured 8 fish (Table 29). Gill netting captured a few different fishes as by-catch; channel catfish were the only species that accounted for a significant number of fish ( 11 fish captured; Table 30). The saugeye captured represented 3 different age classes of fish (age- 0 , age-2, and age- 4 ; Table 31) and relative weights were good for all fish less than 18.0 in (Table 32). Saugeye $\geq 18.0$ in had only moderate relative weights.

## Clear Creek Lake (40a)

## Black bass sampling (Spring/Fall)

On 03 May, Clear Creek lake was diurnally electrofished for an assessment of the largemouth bass population. During this sampling event 128 fish were collected ranging in size from 2.0 to 20.0 in (Table 33). Apart from the 12.0 - to 14.9 -in size class of fish, all catch rates were down in 2021 over previous years (Table 34). Similarly, PSD and $\mathrm{RSD}_{15}$ values were lower than historical norms (Table 35). These lower catch rates resulted in a "Fair" assessment in 2021 (Table 36).

## Channel Catfish (Fall)

On 27 of October, 4-50-hook trot lines were set on Clear Creek Lake to begin assessment of the use of channel catfish nesting boxes in the lake. In total, 27 fish were caught ranging in size from 16.0 to 21.0 in (Table 37). Weights of these fish were in the upper 80 percentile (Table 38). Ultimately, trot lines have proven to be ineffective
at this point in determining the successes of the channel catfish nesting boxes. It is believed that the hook size used was likely too large for the smaller fish that would be the result of the catfish nesting box experiment.

## Greenbo Lake (181a)

## Black bass sampling (Spring/Fall)

On 30 April, Greenbo Lake was diurnally electrofished for an assessment of the largemouth bass population. In total, 314 fish were captured ranging in size from 2.0 to 23.0 in (Table 39). Except for the 12.0- to 14.9-in class of fish, all size classes had similar or higher results when compared to previous years (Table 40). PSD values were similar to previous years, but $\mathrm{RSD}_{15}$ values were significantly higher, indicating a better population of fish over 15.0 in when compares to past years (Table 41). During the fall, a sample of fish was collected to determine age and growth characteristics of the largemouth bass. This sample demonstrated that fish could reach legal size (12.0 in) as early as their $3^{\text {rd }}$ year, but on average it took 4 years to hit this size (Table 42). Females of this population seemed to grow faster than the males, but low sample numbers should raise a bit of caution when examining this data (Table 43). These age and growth characteristics coupled with the spring catch data have resulted in an assessment rating of "good" for the largemouth bass population at Greenbo Lake when compared to other lakes of similar size (Table 44).

On 30 September, the lake was sampled to determine relative weights and the strength of the spawning class. During this sampling period we collected 192 fish ranging in size from 2.0 to 23.0 in (Table 45). Relative weights were in the mid to upper $80 \%$ range and were consistent with previous years' samples (Table 46). Assessment of the spawning class showed a slightly higher than normal year class of fish produced (Table 47).

## Sunfish

On 24 May, Greenbo Lake was diurnally electrofished for assessment of the bluegill and redear sunfish populations. During this sampling period, 222 bluegill and 173 redear sunfish were collected (Table 48). For the bluegill, this sample was a little lower than previous years, except for the larger fish which were slightly higher than average (Table 49). Similarly, PSD values were right at average, but the $\mathrm{RSD}_{8}$ values were significantly higher than previous years (Table 50). Catch rates of fish over 6.0 in and 8.0 in were fair and excellent, respectively (Table 51). Redear sunfish samples were much higher than previous years, with all inch class groups exceeding the averages apart from the larger fish which just met the average (Table 52). Because of the high numbers of smaller fish collected, PSD and $\mathrm{RSD}_{9}$ values were significantly lower than previous years (Table 53). With this being said, catch rates of fish over 8.0 in and 10.0 in were excellent and good, respectively (Table 54).

## Mill Creek Lake (41a)

Black bass sampling (Spring)
On 05 May, Mill Creek Lake was diurnally electrofished for an assessment of the largemouth bass population. In total, 238 fish were collected ranging in size from 2.0 to 21.0 in (Table 55). Samples in the lake continue to be on track or better than previous years when looking at catch rates by inch classes (Table 56) or PSD and RSD 15 values (Table 57). The overall assessment of the largemouth bass population was "good" but produced an excellent rating for fish over 20.0 in and a good rating for fish over 15.0 in (Table 58).

## Lake Reba (76a)

## Black bass sampling (Spring/Fall)

On 19 April, Lake Reba was diurnally electrofished for assessment of the largemouth bass fishery. In total, 309 fish were collected ranging in size from 3.0 to 22.0 in . (Table 59). Catch rates by inch class were very similar to previous years (Table 60) but PSD and $\mathrm{RSD}_{15}$ values were slightly lower than the average (Table 61). Overall assessment of the largemouth bass population was "good" for 2021 (Table 62). Fall sampling was used to determine success of the year's spawn and it was on par with previous years (Table 63).

## Sunfish

On 19 May, Lake Reba was diurnally electrofished for an assessment of the sunfish (bluegill and redear sunfish) populations. In total 450 bluegill or redear sunfish were captured ranging in size from 3.0 to 11.0 in (Table 64). Overall catch rates of bluegill were slightly lower than the average of the previous years (Table 65). PSD values were on target with previous years and fish over 8.0 in continued to be collected which is an improvement over
historical trends (Table 66). Catch rates of bluegill over 6.0 in and 8.0 in scored "fair" and "good", respectively (Table 67). In spite of lower catch rates of smaller redear sunfish, catch rates of the bigger fish were well above average (Table 68). Similar to the bluegill, PSD values for redear sunfish were on target with previous years and fish over 10.0 in continued to be collected, showing an improvement over previous years (Table 69). Assessment values for redear sunfish over 8.0 in and 10.0 in were fair and excellent, respectively (Table 70).

## Smokey Valley (36a)

## Black bass sampling (Spring/Fall)

On 29 April, Smoky Valley Lake was diurnally electrofished for assessment of the largemouth bass fishery. In total, 152 fish were captured ranging in size from 3.0 to 22.0 in (Table 71). Catch rates for smaller fish ( $<8.0$ in and 8.011.0 in ) were lower than the ten year average, while catch rates for larger fish (12.0-14.9 in, $\geq 15.0 \mathrm{in}$, and $\geq 20.0 \mathrm{in}$ ) were similar to other years in the 10 year average (Table 72). PSD and $\mathrm{RSD}_{15}$ values were like previous years (Table 73). Overall, the largemouth bass population was rated as "good" (Table 73).

## Lake Wilgreen (131a)

## Saugeye

On the 09 and 10 of November, Lake Wilgreen was gill netted ( 150 ', 5 panel gill nets) and on the 01 November, the lake was nocturnally electrofished (6, 15-minute sampling runs on DC low, 60 pps and $3-4 \mathrm{amps}$ ) for an assessment of the saugeye population and comparison of sampling techniques. Gill netting captured 10 fish across 2 nights and electrofishing captured 7 fish (Table 75). Gill netting captured a few different fishes as by-catch; blue catfish and channel catfish were the only species that accounted for a significant number of fish ( 18 fish captured total; Table 76). The saugeye captured represented 3 different age classes of fish (age-0, age-2, and age-3; Table 77) and relative weights were good for all size classes of fish (Table 78).

Table 1. Yearly summary of sampling conditions by waterbody, species sampled and date.

| Water body | Species | $\begin{gathered} \text { Date } \\ (2021) \end{gathered}$ | Time 24hr | Gear | Weather | Water Temp ( ${ }^{\circ} \mathrm{F}$ ) | Water level | Secchi <br> (in) | Conditions | Pertinent sampling comments |

# SOUTHEASTERN FISHERY DISTRICT 

Project 1: Lake and Tailwater Fishery Surveys

## FINDINGS

Conditions encountered during sampling at southeastern district lakes are listed in Table 1.

## Lake Cumberland (50,250 acres)

Lake levels in Lake Cumberland rose to 705 msl in 2013 and 723 msl in 2014 with the completion of repairs to Wolf Creek Dam. Sampling completed after 2013 was conducted in areas that were sampled prior to 2007. Samples from 2007-2012 were conducted in areas farther downstream in the embayments due to reduced water levels during dam repairs; therefore, any comparisons of the 2007-2012 data should be interpreted accordingly.

## Black Bass Sampling (Spring)

Diurnal electrofishing studies were conducted at Wolf Creek dam, and in the Faubush Creek, Fishing Creek, and Lily Creek embayments of Lake Cumberland during April and May 2021 to assess the black bass populations. The length-frequency and catch-per-unit-effort (CPUE) of the black bass species collected in each area is shown in Table 2 , and the catch-per-hour (by area and length group) of the three black bass species is shown in Tables 3-6. Overall catch rates of largemouth, smallmouth, and spotted bass in 2021 were lower than rates observed in 2019; however, catch rates for the three black bass species remain above average. Catch rates for largemouth bass 12.0-14.9 in showed a marked increase in 2021, and largemouth bass catch rates for fish greater than 15.0 in remain good. Catch rates of smallmouth bass greater than 14.0 in were consistent with previous sampling. Spotted bass catch rates declined across all size classes in 2021, with a large decrease in the fish less than 8.0 in . Table 7 compares the catch-per-hour by length group of black bass in Lake Cumberland to other SEFD lakes sampled in 2021.

Largemouth bass catch rates greatly exceeded three of the four CPUE management objectives, with only the catch rate of fish greater than 20.0 in failing to meet the objective (Table 8). In addition, largemouth bass exceeded the management objective for growth, with the mean length at age-3 being 14.1 in (Table 8 ). Spotted bass exceeded all three catch rate management objectives (Table 9), while the smallmouth bass population only met the CPUE management objective for fish over 14.0 in (Table 10).

Largemouth bass and smallmouth bass populations exhibited excellent size structure, with a PSD value of 86 ( $\mathrm{RSD}_{15}=49$ ) for largemouth bass and a PSD value of $87\left(\mathrm{RSD}_{14}=74\right)$ for smallmouth bass (Table 11). Spotted bass populations also had a good size structure ( $\mathrm{PSD}=67, \mathrm{RSD}_{14}=16$; Table 11). Table 12 compares the size structure of black bass populations in Lake Cumberland to other SEFD lakes sampled in 2021.

## Black Bass Sampling (Fall)

Diurnal electrofishing was conducted in the Fishing Creek embayment on 29 September 2021 to index largemouth bass year class strength (Tables 13 and 14). Catch rates of age-0 largemouth bass were higher in 2021 than in previous years (Table 14). Table 15 compares the CPUE of age-0 largemouth bass in Lake Cumberland to other SEFD lakes sampled in fall 2021. Relative weight (Wr) values for largemouth bass and spotted bass collected during the September sampling are shown in Table 16. Table 17 compares Wr values for black bass in Lake Cumberland to other SEFD lakes sampled in fall 2021. Age-growth data from largemouth bass collected in 2021 from Lake Cumberland is shown in Table 18. Growth rates for largemouth bass in Lake Cumberland remain good, with bass reaching 14.1 in by age- 3 .

## Crappie Sampling

Fall trap netting was conducted in the Fishing Creek and Wolf Creek embayments of Lake Cumberland during October 2021 to assess the crappie population. Length frequency and CPUE for black and white crappie from each area are shown in Table 19. The PSD and $\mathrm{RSD}_{10}$ values for white and black crappie are shown in Table 20. Agegrowth data from white and black crappie collected in 2021 are shown in Tables 21 and 22, respectively. Age-2 white crappie ( $73 \%$ ) dominated the white crappie catch (Table 23), which corresponds with the high catch rates of age-0 fish in 2019. Age-1 and age-2 black crappie comprised $64 \%$ of the black crappie catch, and age- 0 fish
comprised an additional $23 \%$ of the catch (Table 24). The crappie population assessments (white and black) are shown in Table 25, with both species rating fair. The crappie population met two of the five management objectives (Table 26). Relative weight (Wr) values for black and white crappie are shown in Table 27. Although the number of larger crappie was relatively low in the trap net samples, angler reports and observed crappie collected during other routine sampling at the lake indicates that the crappie population is doing well.

## Striped Bass Sampling

Gill nets were used in late November and early December 2021 to evaluate the striped bass population in Lake Cumberland. Twenty net-nights captured 109 striped bass for a catch rate of 5.5 fish $/ \mathrm{nn}$. Length-frequency and CPUE of striped bass are shown in Table 28. Striped bass ranged from 8.0 to 31.0 in with the mode being the 27.0in class ( 23 fish). Three of the four management objectives were met for the striped bass population, with the CPUE of age-1 fish failing to meet the objective (Table 29). The age-growth data for striped bass collected during 2021 is shown in Table 30. Seven year-classes were represented in the catch (Table 31). The 2017-year class (age-4) remains strong and was the most abundant year class collected ( $32 \%$; Table 31). The 2020-year class (age-1 fish) comprised an additional $20 \%$ of the population (Table 31). The mean length of age- $2+$ fish at capture ( 2019 year class) was 24.0 in, which exceeded the growth objective ( 21.0 in ) for the striped bass fishery (Table 29). The striped bass assessment score was 12 (rating=good; Table 32). Striped bass relative weight (Wr) values are shown in Table 33 , and values were consistent across all size classes.

## Cumberland Tailwater

## Trout Sampling (Fall)

Nocturnal electrofishing sampling was conducted November 7 and 82021 to assess the trout population in the Lake Cumberland tailwater. Electrofishing was completed in seven different areas of the tailwater. Table 34 has the length-frequency and CPUE for the three trout species that were collected in each area. Cutthroat trout, which were first introduced in March 2019 and received an additional stocking of 6,225 fish in 2021, were not observed during the fall sampling. Only one brook trout was observed during sampling. Catch rates of rainbow trout increased across all size groups, except the 18.0-19.9 in group, which decreased compared to rates observed in 2020 (Table 35). Although brown trout catch rates for fish less than 20.0 in improved in 2021, population numbers remain well below the historic average (Table 36). In addition, no brown trout over 20.0 in were observed during the sample. Relative weight (Wr) values for each trout species are shown in Table 37.

## Laurel River Lake (6,060 acres)

## Black Bass Sampling (Spring)

Electrofishing sampling was conducted during April and May 2021 to assess the black bass population in Laurel River Lake. Electrofishing was conducted in four areas of the lake: 1) dam, 2) Spruce Creek, 3) Laurel River arm, and 4) upper Craigs Creek. Length-frequency and CPUE of the three black bass species collected in each area is shown in Table 38. The catch-per-hour (by area and length group) of the three black bass species are shown in Tables 39-42. Catch rates for all three species of black bass increased in 2021. Largemouth bass catch rates, which increased for the third consecutive year, were driven by increases in 12.0 - to 15.0 -in fish and fish greater than 15.0 in. Changes in the catch rates of spotted bass were due to increases in the number of fish in the $11.0-$ to 14.0 -in range. Smallmouth bass catch rates showed an increase in all size classes over 8.0 in . Table 7 compares the catch-per-hour by length group of black bass in Laurel River Lake to other SEFD lakes sampled in spring 2021.

The largemouth bass population met three of the four catch rate objectives, with the CPUE of largemouth bass over 20.0 in ( 0.0 fish $/ \mathrm{hr}$ ) failing to meet the objective ( 0.5 fish $/ \mathrm{hr}$; Table 43 ). Spotted bass met two of the three catch rate management objectives, with the catch rate of age-1 fish failing to meet the objective (Table 44). The smallmouth bass population met one of the catch rate management objectives, with the catch rate of fish over 14.0 in meeting the objective (Table 45).

Size structure values were excellent for largemouth bass ( $\mathrm{PSD}=76, \mathrm{RSD}_{15}=21$ ) and smallmouth bass ( $\mathrm{PSD}=74$, RSD $_{14}=55$; Table 46). Spotted bass exhibited good size structure with a PSD of 57 and an RSD $_{14}$ of 5 (Table 46). Table 12 compares the size structure values of black bass populations in Laurel River Lake to other SEFD lakes sampled in 2021.

## Black Bass Sampling (Fall)

Diurnal electrofishing was conducted in the Laurel River arm on 5 October 2021 to index largemouth bass year class strength (Tables 47 and 48). Age-0 catch rates in 2021 were the highest observed rates at Laurel River Lake (Table 48). Table 15 compares the CPUE of age-0 largemouth bass in Laurel River Lake to other SEFD lakes sampled in fall 2021. Relative weight (Wr) values for largemouth and spotted bass collected during October sampling are shown in Table 49. Table 17 compares Wr values for black bass in Laurel River Lake to other SEFD lakes sampled in fall 2021.

## Walleye Sampling

Gill nets were used in November 2021 to evaluate the walleye population in Laurel River Lake. A total of 102 walleye were captured in 8 net-nights ( nn ) for a catch rate of 12.8 fish $/ \mathrm{nn}$. Length frequency and CPUE of walleye is shown in Table 50. Walleye ranged from 11.0-22.0 in with the mode being the 20.0-in class ( 24 fish). All of the catch rate management objectives for walleye were met in 2021 (Table 51). Age-growth data for male and female walleye are shown in Tables 52 and 53, respectively. The age-growth for both sexes combined is shown in Table 54. Eight year-classes were represented in the catch, with age-1 (2020-year class) walleye comprising $37 \%$ of the catch, and the 2017-year class accounted for an additional $34 \%$ of the catch (Table 55). The walleye assessment score was 16 (rating=excellent; Table 56). Mean length of age-2+ walleye at capture ( 19.5 in ) surpassed the growth objective of 18.0 in (Table 51). Relative weight (Wr) values for walleye are shown in Table 57.

## Cedar Creek Lake (784 acres; Lincoln Co.)

## Black Bass Sampling (Spring)

Diurnal electrofishing was conducted on 20 April 2021 to assess the largemouth bass population in Cedar Creek Lake. The length-frequency and CPUE of largemouth bass is shown in Table 58. Size structure of largemouth bass was excellent ( $\mathrm{PSD}=79, \mathrm{RSD}_{15}=55$; Table 59). Table 12 compares the size structure values of largemouth bass populations in Cedar Creek Lake to other SEFD lakes sampled in 2021. The catch-per-hour (by length group) of largemouth bass for 2012-2021 is shown in Table 60. Overall catch rates of largemouth bass in Cedar Creek Lake decreased in 2021, largely due to reduced catch rates of fish in the 8.0 - to 15.0-in range (Table 60). Catch rates of bass over 15.0 in and greater than 20.0 in increased in 2021 (Table 60). Table 7 compares the catch-per-hour by length group of largemouth bass in Cedar Creek Lake to other SEFD lakes sampled in 2021. All four CPUE management objectives were exceeded for the largemouth bass population (Table 61).

## Black Bass Sampling (Fall)

Diurnal electrofishing was conducted on 30 September 2021 to index the largemouth bass year-class strength (Tables 62 and 63). Catch rates of age-0 largemouth bass in 2021 were higher than in 2020 (Table 63). Table 15 compares the CPUE of age-0 largemouth bass in Cedar Creek Lake to other SEFD lakes sampled in fall 2021. Relative weight (Wr) values for largemouth bass are found in Table 64. Table 17 compares Wr values for largemouth bass in Cedar Creek Lake to other SEFD lakes sampled in fall 2021.

## Bluegill/Redear Sunfish Sampling

Diurnal electrofishing was conducted on 19 May 2021 to assess the bluegill and redear sunfish populations in Cedar Creek Lake. The length-frequency and CPUE of bluegill and redear sunfish is shown in Table 65. The catch-perhour (by length group) of bluegill and redear sunfish is shown in Table 66. Catch rates remain variable for the sunfish population in the lake. Bluegill catch rates have been declining, and no fish over 6.0 in were collected during sampling. The redear sunfish population has increased in both numbers and sizes over the last three years. PSD and RSD values for bluegill and redear sunfish are shown in Table 67. The bluegill population exhibited a poor size structure $\left(\mathrm{PSD}=6, \mathrm{RSD}_{8}=0\right.$; Table 67). The redear sunfish population exhibited a good size structure ( $\mathrm{PSD}=52, \mathrm{RSD}_{9}=9$; Table 67). Age-growth for bluegill collected during fall 2021 is shown in Table 68. The bluegill population assessment score was 5 (rating=poor; Table 69). Age-growth for redear sunfish collected during fall 2021 is shown in Table 70.

The redear sunfish population assessment score was 10 (rating=good; Table 71), with the score being largely influenced by the catch rates of fish over 8.0 and 10.0 in . Relative weight values for bluegill and redear sunfish are shown in Table 72.

## Chenoa Lake (33 acres; Bell County)

## Largemouth Bass Sampling (Spring)

Diurnal electrofishing was conducted on 13 April 2021 at Chenoa Lake to assess the largemouth bass population. Length frequency and CPUE for largemouth bass is shown in Table 73. Catch rates for largemouth bass were considerably higher in 2021 than observed in 2017 (Table 73). Catch-per-hour (by length group) for largemouth bass is shown in Table 74. The largemouth bass size structure was fair, with a PSD value of $49\left(\mathrm{RSD}_{15}=17\right.$; Table 75$)$.

## Bluegill/Redear Sunfish Sampling

Diurnal electrofishing was conducted on 18 May 2021 at Chenoa Lake to assess the bluegill and redear sunfish populations. Length-frequency and CPUE for bluegill and redear sunfish is shown in Table 76. Catch-per-hour (by length group) for bluegill and redear sunfish is in Table 77. The bluegill population exhibited a fair size structure $\left(\mathrm{PSD}=37, \mathrm{RSD}_{8}=4\right)$ and the redear sunfish population exhibited a good size structure $\left(\mathrm{PSD}=67, \mathrm{RSD}_{9}=30\right.$; Table 78).

Age-growth for bluegill and redear sunfish collected during fall 2021 is shown in Tables 79 and 80, respectively. The bluegill population assessment score was 9 (rating=fair; Table 81). The redear sunfish population assessment score was 8 (rating=fair; Table 82). Relative weights (Wr) for bluegill and redear sunfish are shown in Table 83.

## Dale Hollow Lake (6,614 acres; Clinton County; Kentucky Portion)

## Black Bass Sampling (Spring)

Diurnal electrofishing was conducted on 26 April 2021 in the Illwill Creek and Little Sulphur Creek embayments of Dale Hollow Lake to assess the black bass population. Length frequency and CPUE for the three black bass species are shown in Table 84. Catch rates for largemouth and smallmouth bass in 2021 were considerably higher than rates observed in 2018, while catch rates for spotted bass were lower than observed in 2018. The catch-per-hour by length group of the three black bass species are shown in Tables 85-87. Largemouth and smallmouth bass exhibited an excellent size structure, with largemouth bass having a PSD value of $92\left(\mathrm{RSD}_{15}=64\right)$ and smallmouth bass having a PSD value of $81\left(\mathrm{RSD}_{14}=70\right.$; Table 88$)$. These values would typically represent a population that is too heavily skewed towards large fish, but the lack of smaller fish in this case was most likely due to poor sampling habitat for that size of fish. The size structure of spotted bass was poor, having a PSD value of 52 but an $\mathrm{RSD}_{14}$ value of 0 ; Table 88).

## Lake Linville (356 acres; Rockcastle County)

## Black Bass Sampling (Spring)

Diurnal electrofishing was conducted on 12 April 2021 at Lake Linville to assess the black bass population. Length frequency and CPUE for the black bass populations are shown in Tables 89-91. The population assessment for largemouth bass is shown in Table 92. All five management objectives were met or exceeded. The size structure for the largemouth bass population was good with a PSD value of $70\left(\operatorname{RSD}_{15}=15\right)$ and the spotted bass population is comprised of small individuals ( $\mathrm{PSD}=42, \mathrm{RSD}_{14}=0$; Table 93).

## Wood Creek Lake (625 acres; Laurel Co.)

## Black Bass Sampling (Spring)

Diurnal electrofishing was conducted on 15 April 2021 in the Pump Station and Dock areas of Wood Creek Lake to assess the black bass population. Length frequency and CPUE for black bass are shown in Table 94. The size structure for largemouth and spotted bass was poor, with largemouth bass having a PSD value of $25\left(\mathrm{RSD}_{15}=10\right)$ and spotted bass having a PSD of $33\left(\operatorname{RSD}_{14}=0\right.$; Table 95$)$.

Table 12 compares the size structure values of black bass populations in Wood Creek Lake to other SEFD lakes sampled in 2021. Catch-per-hour (by length group) for largemouth and spotted bass are shown in Tables 96 and 97, respectively. Table 7 compares the catch-per-hour by length group of black bass in Wood Creek Lake to other SEFD lakes sampled in 2021. The largemouth bass population assessment is shown in Table 98, with two of the four catch rate management objectives met. The largemouth bass population rated "Fair" in 2021.

Black Bass Sampling (Fall)
Diurnal electrofishing was conducted on 29 September 2021 in the Pump Station and Dock areas of Wood Creek Lake to index largemouth bass year class strength (Tables 99 and 100). Catch rates of age-0 largemouth bass in 2021 were consistent with catch rates observed over the last three years (Table 100). Table 15 compares the CPUE of age-0 largemouth bass in Wood Creek Lake to other SEFD lakes sampled in fall 2021. Relative weight values for largemouth and spotted bass in Wood Creek are shown in Table 101. Table 17 compares Wr values for black bass in Wood Creek Lake to other SEFD lakes sampled in fall 2021.

Table 1. Summary of sampling conditions by waterbody, species sampled, and date for the Southeastern Fisheries District in 2021.

| Water body Location | Species | Date | Time <br> (24hr) | Gear | Weather | Water temp. F | Water level | Secchi <br> (in) | Conditions | Pertinent sampling comments |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Lake Cumberland |  |  |  |  |  |  |  |  |  |  |
| Dam | Black bass | 4/27/2021 | 945 | shock | Sunny, 66, S w inds at 7 mph | 62 | 723 | 36 | good | Only 4 runs due to boat shifter cable breakage |
| Faubush Creek | Black bass | 4/30/2021 | 955 | shock | Mostly sunny, 60s, WNW w inds $5-10 \mathrm{mph}$ | 62 | 722 | 18 | fair | Water w as murkier than usual |
| Fishing Creek | Black bass | 5/7/2021 | 910 | shock | Sunny, low $50 \mathrm{~s}, \mathrm{~W}$ w inds at 8 mph | 63 | 723 | 36 | good |  |
| Lily Creek | Black bass | 5/11/2021 | 1030 | shock | Clear, sunny, $50 \mathrm{~s}, \mathrm{Nw}$ inds at 7 mph | 63 | 723 | 48 | good |  |
| Fishing Creek | Black bass | 9/29/2021 | 905 | shock | Foggy and then sunny, 60s | 74 | 701 | 30 | good |  |

## EASTERN FISHERY DISTRICT

Project 1: Lake and Tailwater Fishery Surveys

## FINDINGS

Table 1 shows sampling conditions by water body for eastern fishery district lakes in 2021.

## Buckhorn Lake

## Muskellunge

Our first attempt at late-winter muskie sampling was ineffective due to colder than normal temperatures and lake ice (Tables 2-4). No additional attempts were made due to high water levels for the remainder of the spring season.

## Black bass

Spring nocturnal electrofishing studies were conducted in the upper and lower sections of the lake during April 2021 to assess the black bass populations. The overall largemouth bass catch rate ( $95.0 \mathrm{fish} / \mathrm{hr}$; Table 5) was down slightly from recent years (Table 6). This is potentially due to lower than normal water levels at the time of spring sampling effort. Our boats were not able to reach the backs of coves where more fish are normally collected. Fish in the $<8.0$-in and 8.0 - to 11.9 -in length groups were most affected ( 32.5 and 38.0 fish $/ \mathrm{hr}$, respectively). Catch rates for the other three remaining length groups (Table 6) were down slightly from most recent years sampling but within the range of observed values through time. Size structure indices were similar to previous years (PSD=39, RSD 15 $=3$; Table 7) and indicative of a population skewed towards smaller individuals. The bass population rates "Fair" based on assessment parameters (Table 8).

Fall nocturnal electrofishing was completed for black bass to determine length frequency and year class strength. Length-frequency data shows that the highest density of fish in the fall 2021 sample ranged from 8.0 to 12.0 inches in length (Table 9). Catch rates of age-0 largemouth bass ( 58.8 fish $/ \mathrm{hr}$ ) were similar to the results of the fall 2020 survey. Both surveys were down considerably in relation to the catch rates observed over the last several years (Table 10). Mean age-0 largemouth bass length (4.9 in) was slightly above average. Recruitment has been good in recent years with above average CPUE observed for age-0 fish from 2016-2019.

## Crappie

Trap netting was conducted in the fall to sample white crappie (Tables 11-15). A total of 2,980 fish were collected in 17 net-nights (nn) for a CPUE of 175.5 fish/nn. Age-0 white crappie were the most numerous age class ( $28 \%$ ) with age- 2 and age- 4 classes also well represented at $23 \%$ and $18 \%$, respectively. Catch rates of fish $\geq 8.0$ in (quality size) and fish $\geq 10.0$ in (preferred size) were 74.4 fish $/ \mathrm{hr}$ and $11.0 \mathrm{fish} / \mathrm{hr}$, respectively. The population assessment was "Excellent" for white crappie primarily due to high numbers of each size class. Growth rates for white crappie at Buckhorn Lake are consistently low. Mean total length of age-2 fish at capture was 6.0 in and failed to reach the 9.0 or 10.0 in size desired for commonly used minimum size limits in Kentucky.

Other species stocked in Buckhorn Lake in 2021 included 400 muskellunge ( 9.7 in ) during August and approximately 5,000 rainbow trout ( $8.0-12.0 \mathrm{in}$ ) stocked in the tailwater during the months of April-June and October-November.

## Carr Creek Lake

## Black bass

Spring diurnal electrofishing was completed in April to assess the black bass population. The overall largemouth bass CPUE of 118.0 fish/hr was lower than the last two spring samples but consistent with the long term (18 year) average of 109.2 fish $/ \mathrm{hr}$ (Tables 16 and 17). The recruitment of age- 1 fish has consistently remained high since 2013 and is most likely due to the continuing expansion of hydrilla in the lake. The catch rate of largemouth $\geq 15.0$ in ( $9.0 \mathrm{fish} / \mathrm{hr}$ ) is slightly below the average (Table 17).

Largemouth bass size structure indices were similar to previous years ( $\mathrm{PSD}=41$; $\mathrm{RSD}_{15}=19$; Table 18). The population assessment dipped to "Fair" for largemouth in 2021 (Table 19). Age and growth data has remained fairly consistent since 2013 indicating stable growth rates.

Nocturnal electrofishing was completed in the fall for black bass in October (Tables 20 and 21). Hydrilla continues to dominate shallow, shore-line areas of the lake by late summer into early fall. Zebra mussels first started showing up in 2019 and have reached their apparent carrying capacity. This in turn continues to keep the lake clear, furthering the expansion of the hydrilla. Length frequency for black bass over 11.0 in was low (Table 20). The expansion of hydrilla continues to limit the ability to electrofish shoreline habitat in the fall, likely reducing catch rates of larger fish. Age-0 CPUE ( 19.6 fish $/ \mathrm{hr}$ ) was observed to be below the average of 25.8 fish $/ \mathrm{hr}$ (Table 21). Mean age-0 largemouth bass length ( 5.5 in ) was well above average. Fall YOY sampling suggests an average largemouth bass year class in 2021 with good potential for overwinter survival due to the increase in mean length.

## Walleye

Diurnal electrofishing samples were collected in the early spring for walleye (Tables 22-24). Additionally, during this sampling effort, broodfish were collected for Minor Clark Fish Hatchery. Over multiple days sampling for broodfish, a total of 141 walleye were sampled for a catch rate of 13.8 fish $/ \mathrm{hr}$. The majority of fish were in the 18.0to 22.0 -in size class (Table 22). The total relative weight value was 85 (Table 24) and is down some from last year. This parameter is influenced by the high number of males collected. The $\log _{10}$ length-weight equation for walleye during 2021 sampling was $-3.14+2.75$ ( $\log _{10}$ length).

Grass carp were stocked jointly by KDFWR and the USACE in an effort to help control hydrilla growth. May stockings totaled 208 fish at 10.0 - to 12.0 -in average length. A total of 35,132 ( 1.4 in ) walleye were stocked in May. A redear sunfish stocking program was initiated in October 2018 and stocking continued in 2019 and 2020 with $14,200(1.2 \mathrm{in})$ fish stocked in September of each year. Due to a sudden and unexpected loss of fish at the hatchery, redear sunfish were not stocked in 2021, but stocking is planned to resume in 2022. Due to the recent establishment of zebra mussels, a blue catfish stocking program was initiated in October 2020 and stocking continued in March 2021 with 7,100 ( 6.5 in ) fish. In 2021 a crappie stocking program was initiated with 17,790 black crappie ( 2.5 in ) stocked in August. Tailwater stockings included 4,000 (total) rainbow trout during the months of April, May, June, October, and November.

During 2019, zebra mussels were documented for the first time in the lake, and they became prolific in number by year end. For 2020, the zebra mussel population peaked by early summer and numbers looked to have significantly reduced by fall. As of 2021, the zebra mussel population appears to have reached carrying capacity and has stabilized. This follows several other recent invasive species introductions of purple loosestrife (2013), hydrilla (2008), and alewife (2000) to Carr Creek Lake.

## Cranks Creek Lake

## Black bass

Spring nocturnal electrofishing was completed in May to assess the black bass population. Length distribution and CPUE are presented in Tables 25 and 26. The overall largemouth CPUE of 144.8 fish/hr was down slightly from recent years but within the range of observed values through time. The catch rates for all length groups $\geq 12.0$ in increased slightly since the 2019 spring survey (Table 26). Largemouth bass size structure indices were similar to previous years ( $\mathrm{PSD}=16 ; \mathrm{RSD}_{15}=10$; Table 27). The population assessment remained "Good" for largemouth bass in 2021 (Table 28). Cranks Creek Lake receives limited tournament fishing pressure; however, it is considered a location of high angler harvest of all species. Catch rates drop off quickly once largemouth reach the 12.0-in minimum length limit. Age and growth data over time continues to show that largemouth bass growth at Cranks Creek Lake is slow with bass only reaching a mean length of 10.7 in by age 3 (Table 28).

Fall nocturnal electrofishing was completed in September for black bass to determine length frequency and year class strength (Tables 29 and 30). Age-0 CPUE ( 31.2 fish/hr) was observed to be below average. Mean age-0 length ( 4.4 in ) was average. This lake's weighted regression shows that the YOY year class is often density dependent. Stocking advanced fingerlings in the fall does not always benefit the year class. This is an extremely clear, relatively infertile lake.

Past efforts to apply fertilizer have had little to no effect due to water chemistry. Largemouth bass are the dominant black bass species, and some fish continue to reach trophy-size at this lake. This has resulted in higher success rates for anglers seeking trophy fish compared to most other eastern lakes. In the spring 2021 survey, 23.0-in and 25.0-in largemouth bass were sampled.

Approximately 4,000 rainbow trout (total) were stocked in the lake during the months of January, April, May, and October. Channel catfish ( 2,$460 ; 7.0 \mathrm{in}$ ) were also stocked in October. No vegetation controls were utilized in 2021; however, herbicides have been used when needed in the past, and future work may include a low-rate stocking of grass carp.

## Dewey Lake

## Black bass

During 2021, spring electrofishing samples were completed for black bass to assess the population during April and May. Due to staff availability, weather, rainfall, and water clarity, the spring survey took place over multiple days during daylight hours. These factors likely affected catch rates which were down considerably for the spring (Table 31). The overall CPUE for largemouth bass in the spring was 68.4 fish $/ \mathrm{hr}$, which was well below the lake average of 144.8 fish/hr (Table 32). Largemouth bass size structure indices $\left(\mathrm{PSD}=59\right.$; $\mathrm{RSD}_{15}=20$; Table 33) were similar to previous years, offering anglers good opportunity for catching quality largemouth bass. The spring assessment was "Fair" for largemouth bass (Table 34). The most recent assessments suggest that recruitment of spring age-1 bass is decreasing.

Fall nocturnal electrofishing was completed in October for black bass to determine length frequency and year class strength (Tables 35 and 36). Mean age-0 length in the fall ( 4.9 in ) was slightly above the average of 4.7 in . The total CPUE of age- 0 ( $32.0 \mathrm{fish} / \mathrm{hr}$ ) and age- $0 \geq 5.0$ in ( $15.6 \mathrm{fish} / \mathrm{hr}$ ) fish was below the lake average ( 42.8 and 18.6 fish $/ \mathrm{hr}$, respectively). When fall age- 0 catch data suggest the need for stocking, advanced fingerlings for Dewey Lake can be held over winter for stocking the following spring. Advanced fingerling largemouth bass will be overwintered at Minor Clark fish hatchery and stocked in the spring of 2022.

A total of 11,000 blue catfish (5.0-9.0 in) were stocked in March. An additional 375 muskellunge ( 9.7 in) were stocked in August. A total of 4,000 rainbow trout ( $1,000 / \mathrm{mo} ; 9.3-10.0 \mathrm{in}$ ) were stocked in the Dewey Lake tailwater in April, May, October, and November.

## Fishtrap Lake

## Black bass

Spring diurnal electrofishing was completed in April and May to assess the black bass population (Table 37). Catch rates for all length groups of largemouth bass decreased slightly in 2021 when compared to 2020 data, especially for fish $<8.0$ in (Table 38). PSD data showed a largemouth bass population skewed towards larger sizes (PSD=64, $\mathrm{RSD}_{15}=19$; Table 39). The PSD and $\mathrm{RSD}_{15}$ data was nearly identical to that seen in 2020. The spring assessment was "Fair" for largemouth bass (Table 40). Due to limited staff availability and fluctuating water levels, multiple days were required to survey the upper and lower areas of the lake. Unusually high conductivity ( $787 \mu \mathrm{~S}$ ) could potentially be affecting catch rates with fewer fish than normal in the shallow shoreline areas. The most recent assessments suggest that recruitment of spring age-1 bass had been improving; however, the age-1 CPUE for 2021 was the lowest recorded over the last 11 years (Table 40). The spring sample for 2022 will be closely monitored to see if numbers return to normal.

Fall nocturnal electrofishing was completed in September for black bass to determine length frequency and year class strength (Tables 41 and 42). Mean age- 0 length ( 5.2 in ) in the fall was above average ( 4.9 in ) for the second year in a row. The total CPUE of age-0 ( $40.0 \mathrm{fish} / \mathrm{hr}$ ) and age- $0 \geq 5.0$-in ( 21.6 fish $/ \mathrm{hr}$ ) fish was well below average (101.9 and 48.5 fish/hr, respectively). When fall age- 0 catch data suggest the need for stocking, advanced fingerlings can be stocked in the fall from hatchery-reared stocks. Fishtrap Lake was stocked at approximately 10 fish/ac (9,720 fish) in September of 2021.

A total of 11,508 blue catfish ( 6.5 in ) were stocked in the lake during March. A total of 23,012 hybrid striped bass ( 1.5 in ) were stocked in June. Rainbow trout ( 10,000 total) were stocked in the tailwater in April, May, June, October, and November.

## Crappie

Trap netting was conducted in the fall to assess the white crappie population (Tables 43-47). A total of 179 fish were collected from 1.8-13.1 in for a total CPUE of 7.5 fish $/ \mathrm{nn}$. Size structure indices for white crappie sampled in 2021 ( $\mathrm{PSD}=70, \mathrm{RSD}=38$ ) were nearly identical to values sampled in 2019. Age-0 white crappie was the most numerous age class representing approximately $60 \%$ of the total catch, while age- 3 crappie were the second most numerous age group representing $24 \%$ of the total catch. Recruitment of crappie to age- 1 and older has been in decline for the last several years as over-all fish abundance has declined. The population assessment was once again "Fair" for white crappie. Mean total length of age- 2 fish at capture was 9.5 in , achieving adequate growth to continue to support the current 9.0 -in minimum size limit. White crappie will next be surveyed in 2023.

Fishtrap Lake is an aging reservoir with limited habitat currently available to fish populations lake wide. Reductions in recruitment as well as over-all fish abundance of both bass and crappie populations support the need for fish habitat-improvement projects at this location. EFD staff began implementing improvements during the summer of 2021 with hinged, hardwood trees. These efforts were well received by both anglers and USACE personnel. Further habitat improvement work will continue on a broader scale as more staff and resources become available in the near future.

## Fishpond Lake

## Black bass

Largemouth bass were sampled via nocturnal electrofishing at Fishpond Lake (32 acres) in April 2021. Fish were collected from 5.4-23.2 in (Table 48) and smaller length groups (8.0-11.9 in) showed a decreased CPUE compared to 2019 (Table 49). This lake continues to provide trophy bass with good PSD and RSD 15 values (Table 50). In 2021, largemouth bass data showed an increase in PSD values going from 41 in 2019 to 61 in 2021. RSD 15 values have also increased from 18 in 2019 to 24 in 2021. Both are indicators of a trophy bass fishery. With an $\mathrm{RSD}_{15}$ value of 24 and a CPUE of 9.1 fish $/ \mathrm{hr}$ for $\geq 20.0$-in fish, there is good opportunity for a high angler success rate for larger fish.

A total of 4,000 rainbow trout ( 9.0 in ) are stocked annually during January, April, May, and October. Channel catfish ( 760 fish; 9.0 in ) are stocked every other year. Largemouth bass will be sampled again in 2023.

## Martins Fork Lake

## Black bass

Nocturnal boat electrofishing to sample the black bass population on Martins Fork Lake was conducted on 13 May 2021. A total of 111 largemouth bass were collected in 1.25 hours of spring sampling for a total CPUE of 88.8 fish $/ \mathrm{hr}$ (Table 51). This catch rate was nearly half of the previous sample (2019) but within the range of values observed over time (Table 52). A total of 32 smallmouth bass were collected ranging from only 4.0-10.0 in (Table 51). Size structure indices for largemouth bass continue to decrease over time ( $\mathrm{PSD}=27, \mathrm{RSD}_{15}=5$; Table 53). Martins Fork Lake has a 12.0 -in minimum size limit and offers anglers limited opportunity to catch trophy bass. Age and growth data was last collected in 2020 and growth rates of largemouth bass have slowly decreased with the mean length of age- 3 fish only reaching 10.4 inches in 2021. The spring assessment was "Fair" for largemouth bass (Table 54).

Fall nocturnal electrofishing was completed in September for black bass to determine length frequency and year class strength. Length-frequency data shows that the highest density of largemouth bass fell in the $9.0-$ to 11.0 -in range (Table 55). Mean age-0 largemouth bass length ( 4.9 in ) was slightly above average. The year class strength model indicated that 2021 was an average recruitment year for young-of-year largemouth bass ( $87.2 \mathrm{fish} / \mathrm{hr}$ ) while numbers of fish age- $0 \geq 5.0$ in ( 36.8 fish $/ \mathrm{hr}$ ) were above average (Table 56). No supplemental stocking of age-1 fingerlings was done in the fall.

Like several other flood control reservoirs in the district, Martins Fork Lake is an aging reservoir that is becoming increasingly void of available fish habitat. EFD staff will increase fish habitat improvement efforts here for 2022 as staff and resources allow. The black bass population will be next surveyed in 2022.

## Walleye

During March, a day was utilized to electrofish for walleye broodfish; however, no fish were collected. The nativestrain walleye have been stocked annually since 2013. While electrofishing for black bass species in May, no walleye were observed once again (Table 51). During the fall survey for black bass species in September, 5 walleye were collected ranging from 7.0-8.0 in (Table 55).

A total of 8,652 native strain walleye ( 5.1 in ) were stocked in August. In addition, 6,700 redear sunfish (1.6 in) were stocked in September. Rainbow trout ( 750 fish/mo) were stocked at the tailwater in April, May, June, October, and November.

## Creel Survey

A random, stratified, roving, daytime creel survey was conducted at Martins Fork Lake from April 01 to October 31, 2021 to estimate angling pressure and angler catch/harvest statistics (Tables 57-64). The survey was scheduled for 16 days of each month. Due to the smaller size of this lake, all data collected was from the same geographical section. Total angler counts were conducted at random times during each creel period. All the creel interviews and angler attitude surveys were collected using an iPad. This device had GPS capabilities that recorded coordinates associated with each interview and survey (Figures 1 and 2). Figure 1 provides a visual representation of the distribution of angler interviews across the lake for the entire creel. The same angler could only be interviewed once per fishing trip for creel data. Figure 2 provides a similar representation of the distribution of angler attitude surveys taken during the survey period. Anglers were only surveyed once for the entire season. The first and only additional creel survey conducted at Martins Fork Lake was in 1998.

The result of this most recent survey shows a decline in estimated angling effort since the 1998 survey. There was an estimated 4,018 fishing trips in 2021 ( 12.0 trips/acre) which accounted for a total of 16,883 angler-hours (50.6 man-hours/acre) of effort (Table 57). For 1998, there was an estimated 6,203 fishing trips ( 18.6 trips/acre) which accounted for a total of 21,607 angler-hours ( 64.7 man-hours/acre). Additionally, 2021 estimates for the total number of fish caught $(19,574)$ and harvested $(3,953)$ were also decreases from $1998(26,469$ fish caught and 8,290 harvested). Anglers in 2021 caught an estimated 8,761 largemouth bass ( 26.2 fish/acre; Table 58). These estimates are an increase over 1998 survey where only 5,203 largemouth bass were caught ( 15.6 fish/acre).

In 2021, anglers made an estimated 1643 trips ( $40.9 \%$ ) targeting black bass species and 418 trips ( $10.4 \%$ ) for white crappie (Table 58). During those trips, 6,902 hours were spent targeting black bass species and 1,757 hours were devoted to crappie angling. There were only 0.21 largemouth bass per acre harvested during the survey period and 7.68 white crappie harvested per acre. A readear sunfish stocking program was initiated at Martins Fork Lake in 2019. For the 2021 survey period, an estimated 1,731 redear sunfish were caught ( 5.24 fish/acre) and 451 of these were harvested. Additionally, an estimated 3,151 bluegill were caught ( 9.43 fish/acre) and 658 of them harvested. A total of 903 hours ( 2.7 man-hours/acre) were devoted to panfish angling in 2021.

An angler attitude survey was conducted during the creel to gather standardized information on angler preferences and satisfaction regarding the fishery at Martins Fork Lake (Appendix A). Anglers were surveyed only one time each during the survey period. A total of 133 anglers were interviewed. Seventy-one (53.4\%) anglers fished Martins Fork Lake more than 10 times in a year. The primary species/group fished for was black bass at $77.4 \%$ ( $90.5 \%$ in 1998). Bluegill and redear sunfish were fished for by $42.9 \%$ of all anglers in 2021 and crappie were fished for by $33.1 \%$ of all anglers.

Only $30.4 \%$ of anglers who fished for bass were "very" or "somewhat satisfied" with the bass fishery at Martins Fork Lake. Forty six percent (46\%) of bass anglers were "Neutral" in terms of their level of satisfaction with the bass fishery. Anglers who were "somewhat satisfied" or "somewhat dissatisfied" were almost evenly split at $21.6 \%$ and $20.6 \%$ respectively. Reasons for dissatisfaction were evenly distributed ( $33.3 \%$ each) between "numbers of fish" and "size of fish". Over eighty three percent ( $83.5 \%$ ) of anglers surveyed were satisfied with the current size and creel limits at Martins Fork Lake. Angler preference for walleye has substantially decreased since the last survey dropping from $80.9 \%$ of all anglers in 1998 to only $3.8 \%$ in 2021.

Stockings of Erie-strain walleye were discontinued in 2005 to reestablish a population of native strain walleye to the Upper Cumberland River drainage. Native strain walleye stockings began in Martins Fork Lake in 2013 but the fishery has never recovered and angler effort for the lake walleye fishery has diminished. Anglers who now pursue walleye in the area have transitioned to the immediate tailwaters of the lake and the Cumberland River below in Harlan, KY.

## Pikeville City Lake

## Black bass

Spring diurnal electrofishing was completed in May to assess the black bass population. Fish were sampled from 3.0-21.0 in (Tables 65 and 66). The fishery remains popular with anglers and has numerous large fish as shown by the PSD and $\mathrm{RSD}_{15}$ values (Table 67). The PSD and $\mathrm{RSD}_{15}$ values are high but expected with the current catch-and-release-only management regulation. No fish were observed with disease or health issues during this sampling effort; however, annual recruitment at this lake is lower than similar-sized reservoirs managed under statewide regulations. EFD staff have recommended moving this lake to the trophy bass management regulation ("20 inch minimum size limit with a one fish daily creel limit"). This was discussed at a City Council meeting in the spring but, after receiving questions and resistance from one or few members of the public, the council members decided to table the decision for further discussion and consideration.

The primary fisheries at Pikeville City Lake (20 acres) are largemouth bass, rainbow trout, bluegill, white crappie, common carp, and channel catfish. This lake has a catch-and-release only regulation for largemouth bass and contains gizzard shad. During 2017, some new stocking programs were initiated (rainbow trout and channel catfish). Rainbow trout stockings now total 2,500 fish a year with 1,250 in March and 1,250 in November. A total of 600 channel catfish will be stocked every other year (even years) in summer.

## Paintsville Lake

## Black bass

Boat electrofishing studies were conducted in the upper and lower sections of the lake in April to assess the black bass population. Length-frequency and CPUE of spotted and largemouth bass are shown in Table 68. Catch rates for largemouth bass decreased in 2021, which was primarily due to a decrease in catch rates of fish less than 12.0 in (Table 69). There was a slight increase in catch rate of fish 12.0-14.9 in, the highest since 2015. Largemouth bass exhibited marginal size structure with a population skewed toward smaller fish with a few large fish present $\left(\mathrm{PSD}=34, \mathrm{RSD}_{15}=10\right.$; Table 70). The bass population rates "Fair" based on assessment parameters (Table 71).

Fall nocturnal electrofishing was completed in September for black bass to determine length frequency and year class strength. Length-frequency data shows that the highest density of largemouth bass fell in the $7.0-$ to 11.0 -in range (Table 72). Mean age-0 largemouth bass length ( 4.5 in ) was slightly below average but considerably better than 2020 data. The year class strength model indicated that 2021 was an above average recruitment year for young-of-year largemouth bass ( $81.8 \mathrm{fish} / \mathrm{hr}$ ) while numbers of fish age- $0 \geq 5.0$ in ( $26.7 \mathrm{fish} / \mathrm{hr}$ ) were average (Table 73). No supplemental stocking of age-1 fingerlings was conducted in the fall. The $12.0-$ to $15.0-\mathrm{in}$ slot length limit for largemouth bass was replaced with a minimum length limit of 12.0 in beginning 1 March 2019. The slot length regulation was in effect for 17 years (2002-2018). Bass angler acceptance of the new regulation has been largely positive.

Spring electrofishing was utilized to sample black and white crappie (Tables 72-74). There are black crappie, blacknosed black crappie, and white crappie present in Paintsville Lake ( 1,150 acres). Length-frequency data shows that the highest density of white crappie fell in the 5.0 - to 7.0 -in range (Table 74). Black-nosed crappie were stocked in Paintsville Lake from 2011-2013. Twenty one percent (4) of the black crappie collected during spring sampling were black-nosed black crappie. The white crappie population is currently at a much higher density than black crappie in the lake (Table 74). The catch rate per length group ( $\geq 8.0-\mathrm{in}$ ) by year and species is shown in Table 75. The total CPUE for white crappie ( 281.3 fish/hr) was higher in 2021 than any other survey on record, primarily due to higher numbers of small fish.

Walleye broodfish collection was conducted in March, with only one $7.91-\mathrm{lb}$ female collected.
The lake received a stocking of 10,000 rainbow trout ( 9.7 in ) during February and 10,000 brown trout ( 8.3 in ) in March. In addition, 57,430 walleye ( 1.5 in ) were stocked in May.

The tailwater trout fishery received approximately 14,000 rainbow trout from April to July and September to November. Due to an increase in temperature in the tailwater, the brown trout stocking was permanently removed beginning in 2020.

## Yatesville Lake

## Black bass

Spring nocturnal electrofishing was completed in April to assess the black bass population at Yatesville Lake. Length distribution and CPUE are presented in Tables 77 and 78. The lower lake produced a greater CPUE for largemouth bass versus the upper lake area. The overall largemouth CPUE of 79.0 fish $/ \mathrm{hr}$ was below the lake's historical average of 136.2 fish $/ \mathrm{hr}$. The most notable reduction in catch rate was for largemouth bass $\leq 12.0 \mathrm{in}$. Largemouth bass size structure indices were slightly better than previous years (PSD=49; $\mathrm{RSD}_{15}=21$; Table 79). The population assessment remained "Fair" for largemouth bass again in 2021 (Table 80). Recruitment of spring age-1 largemouth has remained mostly above average since 2015, but declined in 2021. Due to heavy angling pressure via tournaments from spring into fall, the population is monitored closely.

Fall nocturnal electrofishing was completed in October to determine length frequency and year class strength of black bass species. Age and growth data from largemouth bass collected in 2021 is shown in Table 81. Growth rates for largemouth bass have increased, with bass now reaching 12.6 in by age 3. Previous growth rates for largemouth bass were slightly lower with age-3 fish attaining lengths of 11.1 inches in 2015 and 12.4 inches in 2012. Largemouth bass made up the majority of the fall sample ( $98.5 \%$ ) while spotted bass only made up $1.5 \%$ (Table 82). Age-0 overall CPUE ( $52.7 \mathrm{fish} / \mathrm{hr}$ ) and age- $0 \geq 5.0$-in CPUE ( $21.0 \mathrm{fish} / \mathrm{hr}$ ) suggests that the 2021 year class was slightly below average ( 61.0 fish $/ \mathrm{hr}$ and $32.7 \mathrm{fish} / \mathrm{hr}$, respectively; Table 83 ). These values were nearly identical to 2020 data. Mean age- 0 largemouth bass length ( 4.7 in ) was average compared to most years.

A total of $19,476(6.5-\mathrm{in})$ blue catfish were stocked in the lake in October. Rainbow trout were stocked in the tailwater of Yatesville Lake in April-May and October-November ( 750 fish each month except October-1,000).

Table 1. Summary of 2021 sampling conditions by waterbody, species sampled and date.

| Water body | Species | Date | $\begin{gathered} \text { Time } \\ (24 \mathrm{hr}) \end{gathered}$ | Gear | Weather | Water Temp ( ${ }^{\circ} \mathrm{F}$ ) |  | Secchi <br> (in) | Pertinent sampling comments ${ }^{\text {a,b }}$ |

# WESTERN FISHERY DISTRICT 

Project 3: Technical Guidance

## FINDINGS

Table 1. Technical guidance given to pond owners in the Western Fishery District during the 2021 project year (April 1, 2021 - March 31, 2022). Approximately 98 telephone calls to the office regarding technical guidance and stocking were also handled. Additionally, numerous emails were replied to requesting farm pond technical guidance information.

| County <br> Pond Owner | Date of <br> Inspection | Findings | Management Recommendations |
| :---: | :---: | :---: | :---: |

Due to Covid-19 restrictions, no on-site visits were made during this project year

## NORTHWESTERN FISHERY DISTRICT

Project 3: Technical Guidance

## FINDINGS

Requests for technical guidance information were received via e-mails, phone calls, and office visits. Problems included unbalanced populations, new pond construction, stocking, fish disease and fish kills, water quality issues, aquatic vegetation control, and general pond management. Requested information was relayed via phone, e-mail, office visit, and referencing the Pond Management section of the web site. There were two on-site visits conducted in 2021. These were specific to public accessible fishing locations (Table 1).

Table 1. On-site technical guidance provided to pond owners in the Northwestern Fishery District in 2021

| County | Pond/Lake Ow ner | Date | Findings | Recommendations |
| :--- | :--- | :---: | :--- | :--- |
| Hancock | Hancock Co Fiscal Court | (2) | General lake problems/inspections/EF survey | Continue current management, cutrine granular for craw fish |
| Meade | Fort Knox | $(2)$ | Inspect pond construction site/plans/stocking info | General construction recs, fish habitat addition, stocking |
| Henderson | Audubon State Park | (5) | Inspect lake renovation project, renovate fishery | Add fish habitat/CCF spaw ning boxes, construction/stocking info |
| Union | Union Co Air Board | $(2)$ | Inspect lake, map lake | Generate lake contour map for Asian carp rotenone treatment, EF 2022 |
| Webster | Webster Co Fiscal Court | $(2)$ | Inspect lake, map lake | Provide basic guidance and generate contour map, EF spring 2022 |
| McLean | McLean Co Fiscal Court | (2) | Inspect lake, check on vegetation/improvements | Recommend herbicide for veg control, fish habitat and access improvments |
| Daviess | Ow ensboro City | (2) | Inspect vegetation issues at several lakes/fish kill | Recommend herbicide for veg control, fish habitat and access improvments |
| Daviess | Daviess Co Fiscal Court | $8 / 27 / 22$ | Inspect lake for fish kill | Recommend algecide for future issues |
| Hardin | City of Elizabethtow n | $11 / 18 / 22$ | Check on progress of lake renovation | General construction recs, fish habitat addition, stocking |

## SOUTHWESTERN FISHERY DISTRICT

Project 3: Technical Guidance

## FINDINGS

No onsite technical guidance was provided in 2021. Technical guidance responses were through emails, phone calls, texts, and a few office visits. Most issues dealt with fish stocking and aquatic vegetation control.

## CENTRAL FISHERIES DISTRICT

Project 2: Stream Fishery Surveys - Warmwater Streams

FINDINGS

Stream sampling conditions for 2021 are summarized in Table 1.
Diurnal electrofishing was conducted during March 2021 at various locations on Elkhorn Creek. These studies were conducted to assess the black bass, especially smallmouth bass, and rock bass populations. Length distribution and CPUE data of sportfish, including black bass and rock bass from Elkhorn Creek are presented in Table 2.
Smallmouth bass comprised $50 \%$ of the black bass sampled in the North Fork Elkhorn Creek, whereas smallmouth bass comprised $92 \%$ of the black bass sampled on the main stem Elkhorn Creek. Therefore, largemouth bass comprised $50 \%$ of the black bass sampled in the North Fork Elkhorn Creek and $8 \%$ of the black bass sampled in the main stem Elkhorn Creek. The current catch rate of smallmouth bass in the mainstem Elkhorn Creek (Jackson Hole, Peaks Mill, and Hatchery sites; 106.6 fish/hr) is higher than the historical average of $95.1 \mathrm{fish} / \mathrm{hr}$ (Table 3). The current catch rate of rock bass ( 12.2 fish $/ \mathrm{hr}$ ) was lower than the historical catch rate ( 30.2 fish $/ \mathrm{hr}$; Table 4). The smallmouth bass population assessment score for the North Fork Elkhorn Creek was 15 (Table 5), which results in an "Good" rating. The rock bass population assessment score for North Fork Elkhorn Creek was 7, or "Fair" (Table 6). The largemouth bass population assessment score for North Fork Elkhorn Creek was 16 (Table 7), which results in an "Excellent" rating. Fish populations on the North Fork Elkhorn Creek are affected by two dams in the vicinity of the Great Crossing areas. For the main stem Elkhorn Creek, the smallmouth bass population assessment score was 20 (Table 8), which results in an "Excellent" rating. The rock bass population assessment score was 7 (Table 9), which results in a "Fair" rating. Finally, the largemouth bass population assessment score was 9 (Table 10), which results in a "Fair" rating.

Age and growth of smallmouth bass on Elkhorn Creek was completed in 2021. Smallmouth bass ages in Elkhorn Creek ranged from 1-13 years. The age and growth study indicated smallmouth bass reached 12.0 inches at age-5+ and 15.0 inches at age- $7+$. Total annual mortality of age- $2+$ smallmouth bass was estimated at $34.8 \%$. A comprehensive description of these findings is presented in the Stream Investigation Section (F-40-44) Annual Performance Report (Project IV: Warm Water Stream Sport Fish Surveys).

Diurnal electrofishing for black bass and rock bass was conducted during April 2021 at two locations on Floyds Fork. Length distribution and CPUE data of black bass and rock bass from Floyds Fork are presented in Table 11. Smallmouth bass ( $94 \%$ ) comprised the majority of the black bass sampled in Floyds Fork. The catch rate of smallmouth bass on Floyds Fork in 2021 ( $24.0 \mathrm{fish} / \mathrm{hr}$ ) was higher than the historical average ( 16.5 fish $/ \mathrm{hr}$; Table 12). However, the catch rate of rock bass ( 2.7 fish $/ \mathrm{hr}$ ) was lower than the historical average ( 9.8 fish $/ \mathrm{hr}$; Table 13). The smallmouth bass population assessment rating for Floyds Fork was "Good", the average rating observed since 2012 (Table 14). The rock bass and largemouth bass population assessment ratings were "Poor", which is the average rating for both species in the Floyds Fork (Tables 15 and 16).

Rainbow trout were stocked during March, April, and October 2021 in the North Beckley section of Floyds Fork. A total of 3,600 rainbow were stocked (1,200 fish/stocking) that averaged 9.0-10.0 in.

## CENTRAL FISHERIES DISTRICT

Project 3: Technical Guidance

## FINDINGS

A total of 350 phone calls, 200 e-mails, and 1 walk-in office visits concerning farm pond problems were handled this year.

## NORTHEASTERN FISHERY DISTRICT

Project 2: Streams Fishery Surveys

## Trout Stream Temperature Assessments

Temperature loggers were installed in all NEFD trout designated waters. Data collection spanned from May through October. Parched Corn, Chimney Top, and Dog Fork represent the coldest streams in the district. All three streams are at the upper temperature threshold for trout over-summering habitat (Table 1). Multiple loggers were lost due to high flow events and washouts. Overall, trout streams experienced lower maximum temperatures in 2021 compared to the previous few years.

## Trout Stream Usage (Camera Monitoring)

Trail cameras were placed on streams to assess the number of anglers using the trout-stocked waters. Cameras were installed early May and maintained throughout the year. Only one of the three cameras placed at East Fork Indian functioned properly throughout the year. Middle Fork Red River had the most angler use captured on camera for 2021 (Table 2).

Table 1. Monthly breakdown of minimum, average, and maximum temperatures on designated trout streams.

## NORTHEASTERN FISHERY DISTRICT

## Project 3: Technical Guidance

## FINDINGS

In 2021 on-site visits were permanently suspended. Consultations will continue to be handled via telephone and written correspondence. In 2021, roughly 100-125 phone calls and about 20 written correspondences were handled. Most vegetation problems and a few population problems were resolved using email pictures, pond harvest log data or the use of the "Managing Your Farm Ponds" web page. Typical problems responded to include pond stocking, aquatic vegetation problems, undesirable species, fishing information, fish kills, farm pond management, fish pathogens, water quality, pond construction, structural problems with dams, and pond nuisances.

# SOUTHEASTERN FISHERY DISTRICT 

Project 2: Stream Fishery Surveys - Trout Streams

## FINDINGS

## Stream Temperature Monitoring

HOBO MX TidbiT 400 (MX2203) temperature data loggers were deployed in Bark Camp Creek, Cane Creek, Laurel River Lake Tailwaters, Right Fork Buffalo Creek, and War Fork Creek, to evaluate current trout management strategies. Data loggers were deployed at one upstream and one downstream location within each stream except Right Fork Buffalo Creek. Water temperatures ( ${ }^{\circ} \mathrm{F}$ ) were recorded hourly from late-May to early-December in Bark Camp Creek, Cane Creek, and Laurel River tailwaters and from late June to early December in War Fork Creek and Right Fork Buffalo Creek. Temperature data loggers were visually inspected to verify condition and continued submersion mid-August 2021. Trout stream information for each of these streams can be found in Table 1.

## Bark Camp Creek

The upstream location of Bark Camp Creek recorded zero days with daily average temperatures equal to or exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $71.4^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $69.8^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June. The downstream location recorded zero days with daily average temperatures exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $71.9^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $70.6^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June (Table 2 ).

## Cane Creek

The upstream location of Cane Creek recorded a low number of days (9) with daily average temperatures equal to or exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $73.2^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $69.7^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June. The downstream location recorded a low number of days (5) with daily average temperatures exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $72.5^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $70.4^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June (Table 3).

## Laurel River Lake Tailwaters

The upstream location of Laurel River Lake Tailwaters recorded zero days with daily average temperatures equal to or exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $57.3^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $48.8^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June. The downstream location recorded zero number of days with daily average temperatures exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $63.8^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $52.0^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June (Table 4).

## Right Fork Buffalo Creek

The upstream (stocking) location of Right Fork Buffalo Creek recorded a low number of days (21) with daily average temperatures equal to or exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $74.3^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $71.5^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June (Table 5).

## War Fork Creek

The upstream location of War Fork Creek recorded a low number of days (5) with daily average temperatures equal to or exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $72.8^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $71.2^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June. The downstream location recorded zero days with daily average temperatures exceeding $72^{\circ} \mathrm{F}$, a maximum average daily temperature of $70.4^{\circ} \mathrm{F}$ between June and September, a maximum average daily temperature of $67.4^{\circ} \mathrm{F}$ during June, and zero days with an average temperature equal to or exceeding $73^{\circ} \mathrm{F}$ during June (Table 6). Water temperatures in the lower portion of War Fork Creek may be the result of an influx of cooler water from a small spring located by Turkey Foot Campground.

## Trout Stream Classifications

As outlined in the 2020 Trout Streams Program in Kentucky (found on the Kentucky Department of Fish and Wildlife Resources website), trout streams are currently classified as Class I, II, III, and IV streams based on four water temperature parameters: 1) the number of days stream temperatures average above $72^{\circ} \mathrm{F}$ in a calendar year, 2) maximum temperature reached in the period June-September, 3) number of days stream temperatures average equal to or above $73^{\circ} \mathrm{F}$ in the month of June, and 4) maximum stream temperatures in the month of June. Class I streams have a minimal number of days $(<5)$ above $72^{\circ} \mathrm{F}$ in a calendar year and have a maximum temperature that remains below $72^{\circ} \mathrm{F}$ during the period June-September. Class II streams have a low number of days $(<25)$ above $72^{\circ} \mathrm{F}$ in a calendar year and have a maximum temperature that remains below $75^{\circ} \mathrm{F}$ for the period June-September. Class III and Class IV streams have a significant number of days $(>25)$ above $72^{\circ} \mathrm{F}$ in a calendar year and most likely will be unable to provide significant carry-over to the next year. Separation of Class III and IV streams is based on the number of days the stream temperatures remain equal to or greater than $73^{\circ} \mathrm{F}$ in June and the maximum stream temperature in June. Streams categorized as Class III streams have the potential to be stocked in June while Class IV streams are considered too warm to be stocked in June.

Based on these four water temperature parameters, Bark Camp Creek, Laurel River Lake Tailwaters, and War Fork Creek are classified as Class I trout streams, and Cane Creek and Right Fork Buffalo Creek are classified as Class II trout streams (Table 7). Changes to current management strategies for each of these streams are not recommended at this time.

## Trout Stream Utilization Surveys

Browning Dark Ops HD Pro X trail cameras were placed at the Dam Access Area of Laurel River Lake Tailwaters and the Long Bar Fishing Access Area of the Cumberland Tailwaters on June 17, 2021 (one camera at each location) to monitor trout stream utilization. Stream utilization data from each camera was collected monthly from June 2021-February 2022. 255 anglers utilized the Long Bar Fishing Access Area and 82 anglers utilized the Laurel River Tailwaters Dam Access Area between June 2021 and February 2022 (Table 8).

Table 1. Southeastern Fisheries District trout stream information.

| Stream Name | County | Miles of trout <br> fishing water | Location of trout fishery | Type of trout fishery | Stocking Schedule |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Bark Camp Creek | Whitley | 3.9 | Mouth to U.S. Forest Service <br> Road No. 193 | Rainbow Trout put-and-take <br> Brown Trout put-grow-take <br> Seasonal catch and release | March-June, October |
| Cane Creek | Laurel | 6.6 | Mouth to 6.6 mi upstream | Rainbow Trout put-and-take <br> Seasonal catch and release | March-June, October |
| Laurel River Lake | Laurel/ | 1.2 | Dam to 1.2 mi below | Rainbow Trout put-grow-take <br> Brown Trout put-grow-take | March-June, October |
| Tailwaters <br> Right Fork Buffalo <br> Creek | Owsley | 0.2 | Mile 1.9-2.1 | Rainbow Trout put-and-take | April, May |
| War Fork Creek | Jackson | 1.1 | Turkey Foot Recreation Area <br> upstream to Steer Fork | Rainbow Trout put-and-take | March-June, October |

## SOUTHEASTERN FISHERY DISTRICT

Project 3: Technical Guidance

## FINDINGS

Onsite technical guidance was not provided during 2021. Technical guidance requests were handled over the telephone, text, or by written correspondence. Topics encountered and responded to included: fish population balance, aquatic vegetation problems, fish stocking information, water quality problems, and fish disease.

Several other requests for information (approximately 200) about area fisheries and miscellaneous information about fish management in lakes and ponds were handled over the telephone and email.

## EASTERN FISHERY DISTRICT

## Project 3: Technical Guidance

## FINDINGS

On-site technical guidance was not provided in 2021. Additional technical guidance requests were handled over the telephone, walk-in visits, or by written correspondence (Table 1). Topics encountered and responded to included: fish population balance, water quality problems, fish stocking, fish disease, and aquatic vegetation problems.

Several other requests for information about area fisheries and miscellaneous information about fish management in lakes and ponds were handled over the telephone, email, and walk-in visits.
